The F. B. Shuster Co., Established 1866 New Haven, Conn.

Elastic Rotary Blow Riveting Machines, Straighteners and Cutters for strip stocks, hex, squares, and flats as well as rounds, Cotter Pin Machines, Buckle Tongue Machinery, Special Automatic Machinery

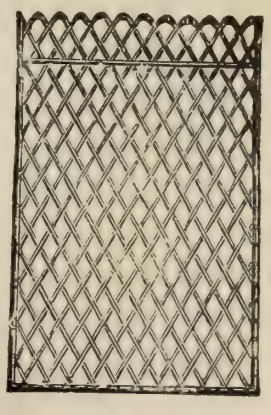
PERFORATED METALS

Describe your need. "We can furnish." Inquiries solicited.

We make any size perforation in any kind of metal required.

Canada Wire Goods Manufacturing Co. - Hamilton

We also manufacture



- Wire Cloth for all purposes
- Concrete Reinforcement
- Molders' Riddles and Bellows
- Metal Clothes Lockers
- Steel Factory Stools
- Window Guards
- Ornamental Wire and Iron Work

No More Broken Windows

The factory or mill lighted by a great number of windows can save a lot of money annually by preventing those windows from breakage. For this purpose nothing equals in economy, efficiency or good appearance

GREENING'S
WIRE WINDOW GUARDS

Once bought and put in place these guards will last a lifetime. Accidental breakage is made almost impossible Nothing can fall out of the windows protected by Greening Guards. They mean a saving in expense and an improvement in appearance from every point of view. And, on account of our enormous output of these and similar goods, our prices are the very lowest procurable.

Write us for Catalogue No. 4 and Samples

"D.L." Standard Metal Lockers

installed in your shop or factory will most certainly economize space and save time, money and contents.

They are now regarded as part of the necessary equipment of every up-to-date shop, and have many points of superiority over ordinary wire and expanded metal lockers.

"D L." Lockers are a protection from fire, prevent petty theft, and are a sanitary prevention for workmen against contagion.

They are strong, durable and well finished, and will surely promote order, tidiness and system in your business.

Send for catalogue "D" and full details

BUSINESS CHANCES.

WANTED, by an experienced engineer in Germany, reliable business connection to start and run an importing office between Germany, Canada and England, as engineering and commission. Same can bring a number of important German agencies. Box 55, CANADIAN MACHINERY AND MANUFACTURING NEWS, 88 Fleet Street, London, England. (5)

POSITIONS WANTED.

FOUNDRY FOREMAN open for engagement or as assistant in large shop. Machinery line. Best of references. Box 110, CANADIAN MACHINERY, Toronto.

PAINTER AND LETTERER, 35, wants position as foreman or under. American and Canadian experience with car, locomotive machinery, bridges, etc. Construction firms in States or Canada. Good bonus given for procuring same. At liberty in a month. Write Box 56, CANADIAN MACHINERY, Toronto. (3)

LIVE MAN, thoroughly practical and theoretical. Experienced improving machine shop methods and efficiency. Piece work; time study; demonstrating. Tactful and diplomatic in handling men. Excellent references. Box 108, CANADIAN MACHINERY, Toronto. (2)

MISCELLANEOUS.

A BOOK-KEEPING STAFF IN ITSELF — doing the work with machine-precision and accuracy, the National Cash Register. Write us for demonstration literature. National Cash Register Co., 285 Yonge St., Toronto.

ACCURATE COST KEEPING IS EASY if you have a Dey Cost Keeper. It automatically records actual time spent on each operation down to the decimal fraction of an hour. Several operations of jobs can be recorded on one card. For small firms we recommend this as an excellent combination—employees' time register and cost keeper. Whether you employ a few or hundreds of hands, we can supply you with a machine suited to your requirements. Write for catalog. International Time Recording Company of Canada, Ltd. Office and factory, 29 Alice Street, Toronto.

COPELAND-CHATTERSON SYSTEMS — Short, simple. Adapted to all classes of business. Copeland-Chatterson-Crain, Ltd., Toronto and Ottawa. (tf)

COUNTER CHECK BOOKS — Write us to-day for samples. We are manufacturers of the famous SURETY NON-SMUT duplicating and triplicating Counter Check Books, and Single Carbon Pads in all varieties. Dominion Register Co., Ltd., Toronto.

DOUBLE YOUR FLOOR SPACE. An Otis-Fensom hand-power elevator will double your floor space, enable you to use that upper floor either as stock room or as extra selling space, at the same time increasing space on your ground floor. Costs only $70. Write for catalogue "B." The Otis-Fensom Elevator Co., Traders Bank Building, Toronto. (tf)

ELLIOTT-FISHER STANDARD WRITING-ADDING MACHINES make toil easier. Elliot, Fisher, Limited, Room 314, Stair Building, Toronto.

EGRY business systems are devised to suit every department of every business. They are labor and time savers. Produce results up to the requirements of merchants and manufacturers. Inquire from our nearest office. Egry Register Co., Dayton, Ohio; 123 Bay St., Toronto; 258½ Portage Ave., Winnipeg; 308 Richards St., Vancouver.

FIRE INSURANCE. Insure in the HARTFORD. Agencies everywhere in Canada. (tf)

HUNDREDS OF TYPEWRITERS of every make and condition are being traded in as part payment on the famous MONARCH. Price and quality are the levers we use to prevent over stock. We believe we can give the best bargains in rebuilt typewriters in Canada. A postal will bring our catalogue and full information. THE MONARCH TYPEWRITER CO., Limited, 46 Adelaide Street West, Toronto.

INDISPENSABLE in office, store, home—Canadian Almanac, 1911—a National Directory. Complete classified information on every subject of Dominion importance. Full Postage, Customs, Banking, Insurance, Legal, Educational, Newspaper, Army, Clerical, Government, Particulars of leading Institutions and Societies. Paper Covers, 60c. Cloth, Leather Back, $1. At stationers, or sent postpaid on receipt of price by The Copp-Clark Co., Ltd., Toronto.

MACHINERY

SALESMAN WANTED for machine tools and supplies (specialties) with good practical experience and good trade connections, especially in Ontario; must be order getter and able to work up business. Give full particulars, past experience, salary, etc. Confidential. Apply by letter to SCHUCHARDT & SCHUTTE, 90 West Street, New York. (4)

MISCELLANEOUS.

KAY'S FURNITURE CATALOGUE No. 306 contains 160 pages of fine half-tone engravings of newest designs in Carpets, Rugs, Furniture, Draperies, Wall Papers and Pottery with Cash prices. Write for a copy—it's free. John Kay Company, Ltd., 36 King St. West, Toronto.

MODERN FIREPROOF CONSTRUCTION—Our system of reinforced concrete work, as successfully used in many of Canada's largest buildings, gives better results at lower cost. "A strong statement," you will say. Write us and let us prove our claims. That's fair. Leach Concrete Co., Ltd., 100 King St. West, Toronto. (tf)

MR. BUSINESS MAN, are you progressive? It's up to you to test "Consolidated," our new process carbon paper. Because it costs less. Soft finish, without smutting, and clear, permanent copies. Write for sample sheets and prices. "Consolidated," Stratford, Ont.

MOORE'S NON-LEAKABLE FOUNTAIN PENS. If you have Fountain Pen troubles of your own, the best remedy is to go to your stationer and purchase from him a Moore's Non Leakable Fountain Pen. This is the one pen that gives universal satisfaction and it costs no more than you pay for one not as good. Price $2.50 and upwards. W. J. Gage & Co., Limited, Toronto, Sole Agents for Canada.

MULTIPLE TYPEWRITING and real printing turned out by the Multigraph in your own office will get more business and reduce printing bills—saves 25% to 75% of average annual printing cost on stationery, system forms and circulars. Write for particulars. AMERICAN MULTIGRAPH SALES CO., Limited, 129 Bay Street, Toronto, Ont.

"SYSTEMS" stand for all that is best in loose-leaf binders and supplies, letter-heads, statements and in fact your office stationery of every description. Send us samples of what you are using—we will send you prices that will interest you. Business Systems, Limited, Manufacturing Stationers, Toronto. (tf)

THE "Kalamazoo" Loose Leaf Binder is the only binder that will hold just as many sheets as you actually require and no more. The back is flexible, writing surface flat, alignment perfect. No exposed metal parts or complicated mechanism. Write for booklet. Warwick Bros. & Rutter, Ltd., King and Spadina, Toronto.

WAREHOUSE and Factory Heating Systems. Taylor-Forbes Company, Limited. Supplied by the trade throughout Canada. (tf)

Write Now!

Our Furnaces Heat Steel with the Cheapest Fuel on Earth—
SOFT, SLACK COAL

They are all fired with "American" Mechanical Stokers, which burn bituminous slack coal automatically and without smoke, and give a clear, steady, soft, non-scaling flame. You get increased production, at about one-third to one-half the operating cost of oil or hard coal. This is a fact. If you burn money to heat steel why not burn less of it, and write us at once?

A GOLD MINE

SAVE YOUR IRON

SLY'S PATENT IRON CINDER MILL
Patented, No. 514097. Patented, No. 841728.

may be at your disposal on your very premises. Look out of your side window or back door and see if you have not an accumulation of cupola dump, and other foundry refuse, which is a total loss to you in its present state. Why not add to your profits and install one of the Sly Patent Cinder Mills to reclaim this iron and be astonished at your former loss and pocket the rich returns from your newly-discovered mine.

Sly's Patent Iron Cinder Mill will save 95% of the iron contained in your cupola dump and gangway scrapings and 75% of the coke. Iron is valuable, then why throw it in the dump? Iron recovered by this Mill is better than machinery scrap. Study economy in a foundry and your profits will increase accordingly. Mill will pay for itself three or four times every year, and we have records of Mill paying for itself twelve times a year. Let us know amount of your daily melt and we will quote. *Write for Cinder Mill Catalogue F.*

We also manufacture Cleaning Mills, Dust Arresters, Sand Blast and Foundry Equipment.

Detroit Solvay Coke
AVERAGE ANALYSIS
91% Carbon, 8% Ash and 65/100% Sulphur.
The analysis of contents of every car is shown on every invoice.

Insures Increased Melt
and Extra Fine Castings.

BAIRD & WEST
DETROIT
Sole Selling Agents Detroit Ovens.

The Making of Hollow Castings

The recent introduction of King Kore Kompound has now rendered this, once somewhat difficult, part of Foundry practice comparatively easy.

It has, also, reduced the core expense by more than one-half.

This compound is a black, dry powder, and is used as flour is used, but with one-half the quantity is produced greater and better results.

Its use avoids the danger of swelling or "blowing." The core easily comes out of the casting, and when old cores are ground up, in the rattler, or otherwise, the sand so made is used over again.

The core compound it contains, again becomes a binder under heat of the core oven, as it melts, and so it is used over and over again.

This is Foundry Economy; Flour, Rosin, etc., are now luxuries.

A barrel of King Kore Kompound will be sent "subject to approval" to any inquiring mind.

That is the **Stevens' System** of trying before buying.

I have copies of proportions of compound to sand used and methods followed in core rooms of Foundries in thirteen different States. This information, with other printed matter relative to the subject, will be mailed on request.

I maintain a direct branch at 137 Jarvis St., Mr. J. M. Mayers, Manager, Toronto, Ont., where is stocked a supply of **Foundry Facings, Foundry Supplies, Buffing Compositions,** of my own manufacture.

The stamp of quality pervades them all.

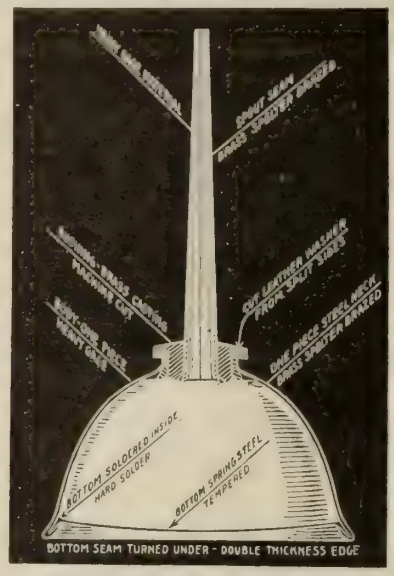
FREDERIC B. STEVENS

Main Office - - - - - - DETROIT, MICH.
Canadian Branch - - - 137 Jarvis Street, TORONTO.

Give the workman the right wheel —right size – right grade—right grit —and insure maximum efficiency in your Grinding Department.

Carborundum Grinding Wheels

Do better, faster and cleaner work under more different conditions than any other grinding wheels ever made.



For instance, just to show the wonderful cutting powers—the versatility and durability of a Carborundum wheel, the foreman of a large machine shop ground a Novo high speed tool, a gray iron casting, a brass casting, a cast steel tool and a bar of bronze.

When the wheel was stopped it was found that there was no sign of glazing and the wheel loss was too small to be noticed.

Carborundum can do the same wonderful work in your shop. Let us know about your grinding and we will help you to get the right wheel in the right place.

The Carborundum Company
NIAGARA FALLS, N.Y.

The Oiler You Will Eventually Use Is

THE GEM BRAZED SEAM OILER
Practically indestructible.
Guaranteed to last.

Write for Booklet "Economy Oilers."

Gem Manufacturing Co.
PITTSBURG, PA.

BROWNING LOCOMOTIVE CRANES

Are built to handle easily the heaviest lifting in logging, contracting enterprises, etc.

Economies of huge proportions are effected in every considerable undertaking, economies that spell profits in the final accounting.

We will gladly give you catalogues and estimates covering whatever work you may be performing.

BROWNING CRANES PERFORM WONDERS.

The Browning Engineering Co.
CLEVELAND : OHIO : U.S.A.

PERFECT CASTINGS

Don't consider a casting like this to be useless—at a slight cost it can be made as good as the **best casting you ever made.**

Don't continue a needless waste. Consider what a saving there is on just one such casting as this. Then consider what a year's saving would be. Then try a can of **Shelton Metallic Filler**

No More Scrap Heap

No More Lost Profits

Shelton Metallic Filler

No More Delayed Shipments

No More Disappointed Customers

This illustration shows how a man saved the above casting from the "scrap-heap." A spatula, a little time, and a little Shelton Metallic Filler were all the requirements necessary to make it a highest quality casting.

Shelton Metallic Filler is guaranteed to fill in and completely obliterate blow holes, sand holes, etc. It becomes part of the casting itself, is durable, and can never be detected. It has been used with great success for many years. **Better write to us at once.**

SHELTON METALLIC FILLER CO

Morse Twist Drill & Machine Co.
New Bedford - Mass. - U.S.A.

Three Minutes' Grinding puts a new and stronger tang on the shank. It fits the lower slot in the socket.

What Do Your Twisted-Off Tangs Cost?

Keep account for a time of the new drills used to replace those thrown into the scrap heap because of twisted-off tangs, and you will see. These scrapped drills are all right in every other respect.

The "PERFECT" Double-Tang Socket

gives a simple, effective, and inexpensive means of eliminating this cost and putting the drills back in money-earning shape. **Write for Folder A.**

Blau-Gas
TRADE MARK

THE SAFEST EASIEST MOST ECONOMICAL AND EFFICIENT METHOD FOR WELDING CUTTING AND BRAZING CAST IRON BRASS COPPER BRONZE STEEL

OXY BLAUGAS

Oxy Blaugas is the Safest method of metal working because Blaugas is the safest gas ever invented.

Oxy Blaugas is the Easiest because the flame can be instantly adjusted. Any mechanic can learn to operate it in a few days.

Oxy Blaugas is the Most Economical because it is 10% hotter than acetylene and one-third cheaper. The work is done quickly and no expert welders are needed. Cost of upkeep nil.

Oxy Blaugas is the most Efficient because Blaugas is ready for use, shipped in steel bottles. There is no generation, no care, and no impurities to affect the flame. **The equipment is portable and can be carried anywhere.**

OXY BLAUGAS WILL MAKE A SOFT, MACHINABLE CAST IRON WELD.

Aluminum welding is also a special feature. We are ready to prove our statements. Let us show you some sample work—then you will buy the machine.

Meantime write now for illustrated Catalog.

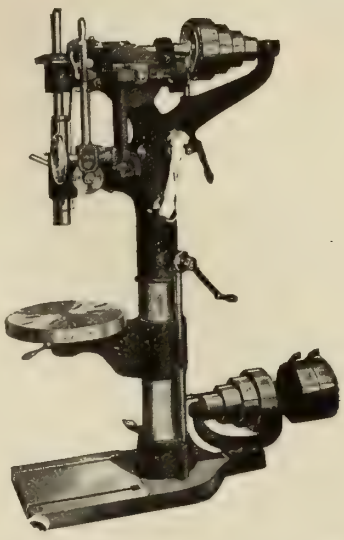
FOX

Multiple Spindle Drills

You are not producing your work at the lowest possible cost unless you are using a **Fox Multiple Drill.**

The machine shown drills 6⅝-inch holes in aluminum, cast iron or steel, and spindles can be set to a 9-inch circle.



We also build machines to drill layouts up to 16x 30 inches, rectangular or irregular, and circles 24 inches in diameter, carrying as large as 1¼ inch drills.

We are introducing a new line in

GRINDING WHEELS:

Dominion Abrasive Wheels

These wheels are made by the vitrified process, recognized as the BEST in the world. We use the very best emery and artificial abrasives combined with a special bond of our own.

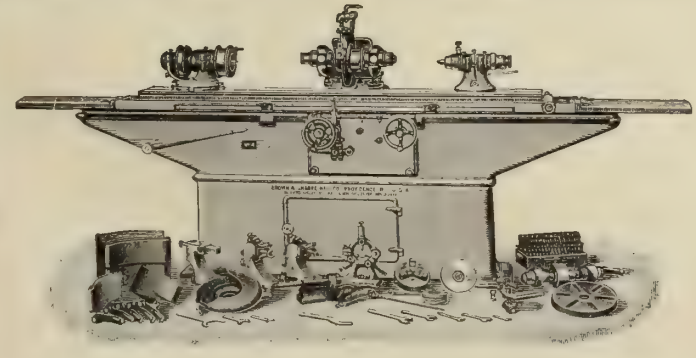
We produce a fast cutting wheel, which will not draw the temper of your tools and which we guarantee to be thoroughly satisfactory.

WRITE US FOR PARTICULARS.

Dominion Abrasive Wheel Co.
LIMITED
New Toronto, Ont.

FIRE BRICK *for* Cupolas

¶ The standard Fire Clays by which all other Clays are judged are those of Pennsylvania.

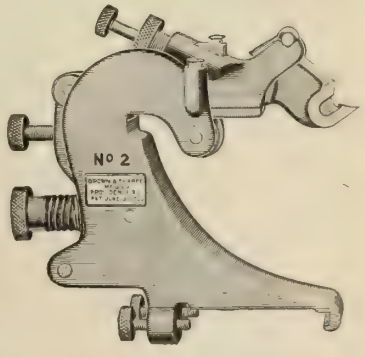


¶ They're the ones from which our Cupola Brick are made.

¶ The cost per thousand means nothing unless you know the results the Brick are giving.

¶ Write us for definite examples of how our material affects your melting costs.

HARBISON-WALKER REFRACTORIES COMPANY,
PITTSBURGH, PENNSYLVANIA



Four Important Features in the Universal Back Rests which present Strong Arguments in Favor of Using

B. & S. Universal Grinding Machines

1. The rests are always ready for new work.
2. The work cannot be ground beyond size.
3. Work is supported from bottom and side.
4. Even pressure is exerted at all times,

We have circulars which explain the rests and machines in full. Sent on request.

FOR SALE BY SUPPLY HOUSES

SAVE MONEY

Cut down your fixed charges by reducing fuel bills, at the same time increasing the efficiency and life of your boilers, by preventing scale from forming in the same.

This can be accomplished by installing the **Webster open type feed water heater, purifier and filter.**

Over 2,000,000 Horse Power of Webster Heaters are demonstrating their superiority over other types of Heaters

The Webster Heaters are made specially to suit the conditions of any individual steam plant.

THE BEST IS NONE TOO GOOD—GET THE BEST

THIS new gap lathe really is the best on the market. Its construction makes it the best. Notice the extra strong gap, giving absolute rigidity. The carriage and apron cannot spring under the most severe strain. The headstock will not chatter. The tailstock is fitted with a quick-acting locking device and is adjusted from the top, saving time to the operator. Eighteen distinct spindle speeds by double back gears. Adjustable to thousandth of an inch both ways by graduated compound rest. Full equipment with each lathe.

Headstock construction prevents chattering, and deep oil chambers fitted with ring oilers make spindles and bearings self-oiling and always well lubricated.

Tailstock of a special type, and sleeve is clamped by a quick acting locking device. Tailstock is secured to bed by bolts adjusted from the top where they are easily accessible.

Bed, non-springing and webbed, and braced to secure rigidity.

Gap, vibration absolutely prevented by use of brace supports to carriage.

Spindle, high carbon hammered steel in solid chilled cast iron bearings, accurately fitted and self oiling.

Carriage and Apron, non-springing under severest strain, full "V" bearings and flat bearings in addition on front ways.

Double Back Gears give eighteen distinct spindle speeds, suiting lathe to work on widely different diameters.

Compound Rest, with graduated base, accurately fitted taper gibs, end adjusted. Screws in both rest and cross slide read to thousandths.

Friction, Safety Feeds, screw and rod feeds cannot be both engaged at the same time. Quick changes of 1¼, 2½ and 5 times thread being cut.

Gears and Racks, cut from solid and steel where necessary.

Screw Cutting, full range of commercial threads provided for.

Equipment, Compound rest, steady rest, follow rest, large and small face plates, wrenches, two-speed, friction countershaft furnished with each lathe.

Accuracy, Strength, Solidity, Wear. These are the paramount features behind all McDougall Machines. Made **to meet extreme demands.**

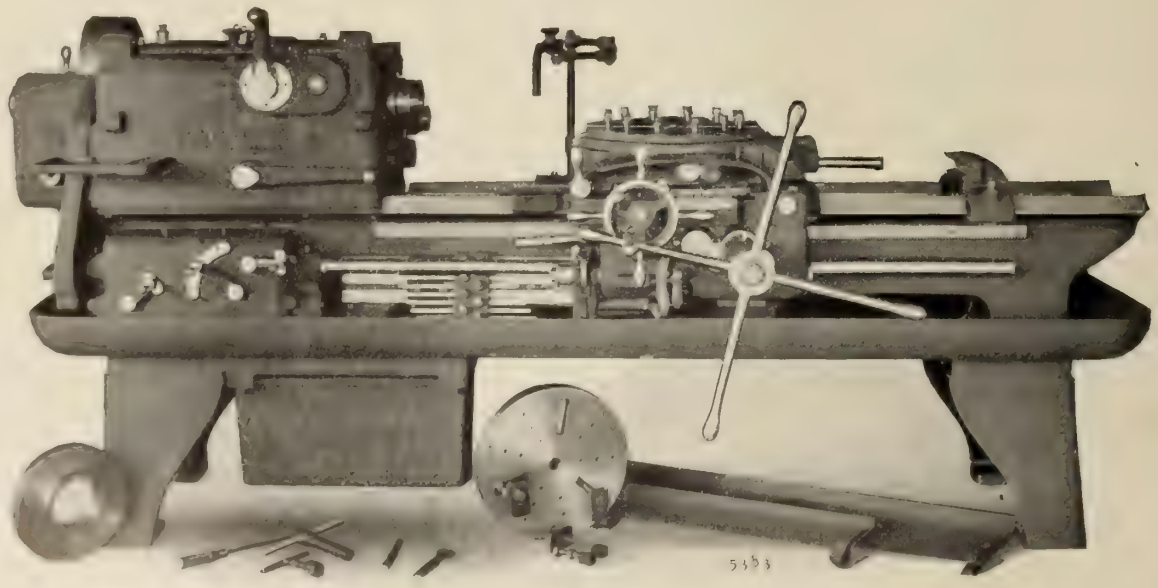
No Time Like the Present

to systemize—to reduce manufacturing costs—to put your product on an even manufacturing basis to meet competition.

The strong bids that exist in current machine practice continually make for a closer cost figure on production. You can meet these figures, and do even better, by installing machines that can handle your work judiciously—with the least expenditure in time, labor and tools—without tying up a lot of necessary capital in tools, jigs and fixtures, any or all of which might become obsolete with a slight change in work. Install

The Turntable Lathe



With Cross-Sliding Turntable

or install several of them, but one machine is sufficient to demonstrate the flexibility and adaptability so necessary to permit ONE machine to handle castings, forgings and rod-work.

The Turntable Lathe is a manufacturing machine that is quickly set up, has a minimum number of tools for the greatest number of operations, readily adapts itself to any manufacturing changes, and assures rapid, accurate production, so that each piece, as it leaves the machine, will be fully finished and interchangeable.

Built in one size—the most practical size—2½x26 in. Swing 20 in.

Do the right thing at the right time and you'll hold a good job;
Specify the right motors now, and save money in your factory.

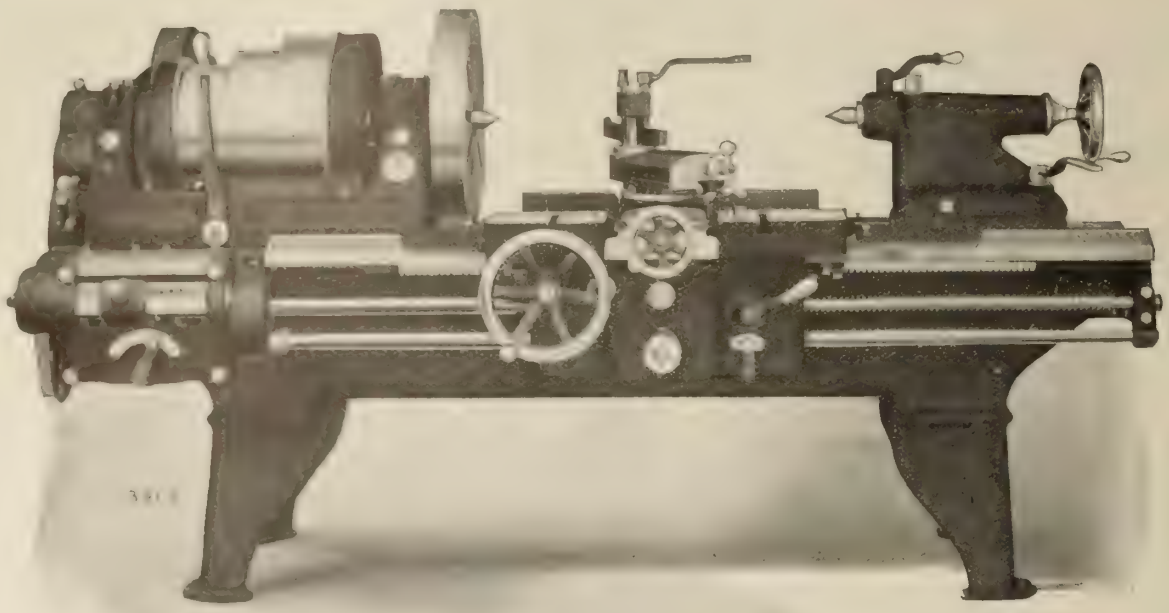
"CCL" Motor Belted to Band Saw.

Westinghouse Type "CCL" Motors

are built for constant speed service on alternating-current circuits. They are of extremely simple construction, having no sliding contacts, and no wearing parts except the bearings which are capable of withstanding long and severe service with no attention other than occasional oiling.

Type "CCL" Motors may be used with perfect safety in locations surrounded by inflammable or explosive materials, as absolute freedom from sparking is assured.

The installation of Type "CCL" Motors in your factory will cut down your attendance and maintenance charges, reduce cost of operation, and increase your profits.



Begin to save money now. Send for Circular 1118.

Cost Reducing Features

An indestructible spindle bearing made of hardened steel and cast iron.

A head construction that gives more effective pulling power at the spindle than any other lathe built.

A patent "Compensating V" that permits four times the bearing area between the carriage and bed found on other lathes.

A carriage in which the tool thrust is taken on a bearing the entire length of the carriage, and which positively will not climb the V.

A double-walled one-piece apron which will last as long as the rest of the lathe.

A quick change gear complete in one unit, giving thirty-six changes with two operating levers.

An offset compound rest which can be used without skinning the operator's knuckles.

The centres set back of the middle of the bed, giving greater swing over carriage and permitting the turning of work up to the maximum swing without the tool overhanging the bed.

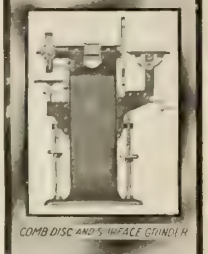
Motor Headstock Speed Lathes and Pattern Makers' Lathes



This lathe is a model of compactness and adaptability to patternshop requirements. Patented improvements in the field design give the motor an exceedingly wide range of speeds. The motor is placed on the bed of the lathe, adding to its superior convenience. Armature and commutator are mounted directly on the spindle, which is journaled in taper bronze bearings, with convenient adjustment for taking up the wear, and end thrust. The entire outfit is incorporated into the design of the lathe, which can be placed in any position desired.

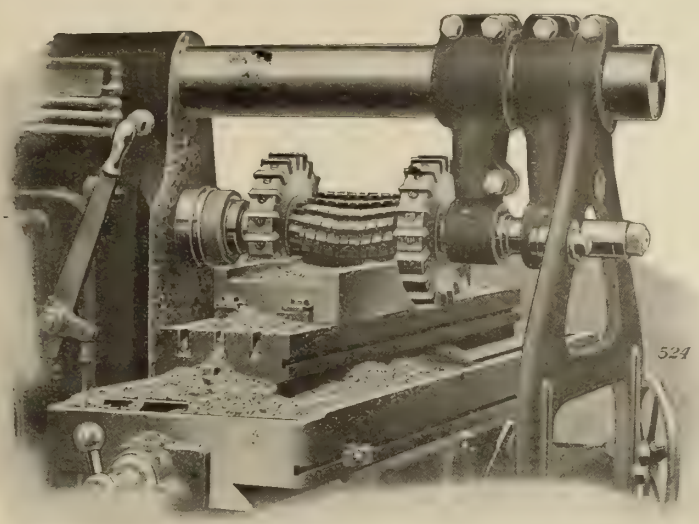
GRINDER LINE

COMB DISC AND SURFACE GRINDER

NO. 2 GRINDER

COMB WET

TAIN LEADERS



The Valley City Combination Disc and Surface Grinder

is an especially advantageous machine for the pattern shop and for all kinds of tool and surface grinding. The very substantial construction, body of machine one solid casting, eliminates vibration and contributes to accurate product. All conveniences—rapid adjusting screws, tilting table, micrometer adjustment for upper table, rest for tool grinding—a complete and efficient machine.
Full line includes Wet and Dry Grinders, Combination Machines, Buffing and Polishing Machines.

Send for Catalogue.

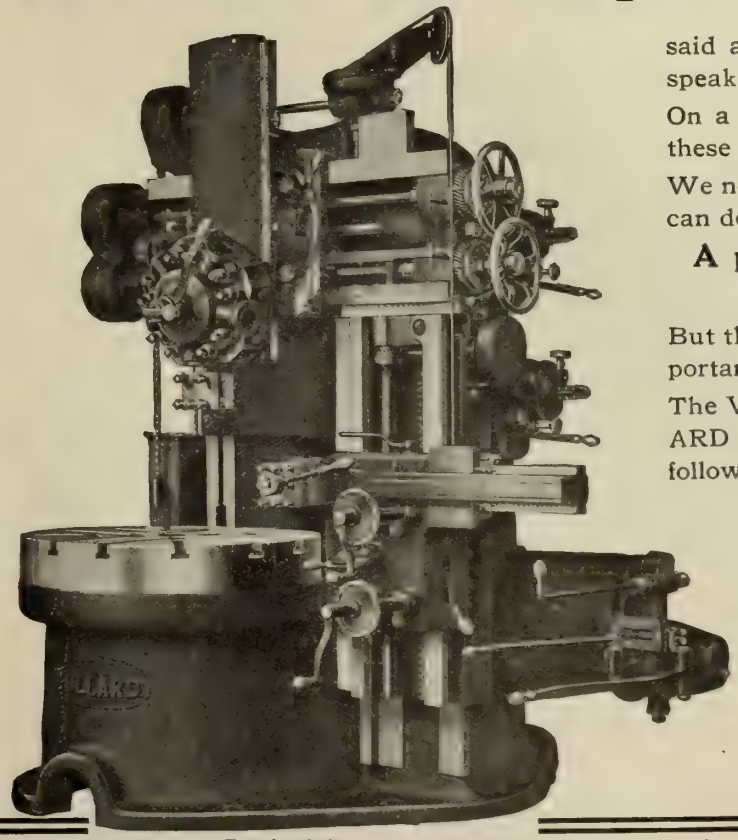
Valley City Machine Works
20 Compau Street, Grand Rapids, Mich.

NINETEEN CUBIC INCHES PER MINUTE

THE total width of surface roughed off at one cut on these gray iron castings is 16½ inches—maximum depth of cut 3-16 in.—length of cut on each piece 8¼ in.—largest cutters 10½ in. diameter, running 21 rev.—6.3 feed.

The pieces are held in a string jig, removed as fast as traversed by the gang and others chucked in their places.

The pieces are made in lots of 125 at a time and an entire lot is regularly milled on a No. 4 Plain High Power Cincinnati Motor Driven Miller at this enormous rate without stopping to sharpen the cutters.



It takes a powerful, rugged machine to do such milling, and it must go through without vibration—otherwise the cutters would be dulled, forcing a reduction in the feed, long before an entire lot of pieces is finished. Our machines are designed for this kind of service.

Ask for our Complete Catalog

The Cincinnati Milling Machine Co., Cincinnati

Canada Agents: H. W. PETRIE, Limited, Toronto, Montreal and Vancouver

"It Has Keyed Up the Whole Shop"

said a prominent Pennsylvania manufacturer, in speaking of the Vertical Turret Lathe.

On a four-foot Boring Mill we formerly did 3 of these pieces in a nine-hour day.

We now get 13 pieces a day from THIS machine and can do better.

A production increase of 425%; a cost reduction of 76%

But there is more to the story than that—more important, perhaps.

The Vertical Turret Lathe has set a new STANDARD in that shop—a faster pace, unconsciously followed by EVERYONE, has been set—"It has keyed up the whole shop!"

Distinctive structural and operative features are responsible for this result.

It is to your interest to know about them.

Let us send you Catalog C-15, which goes into full details.

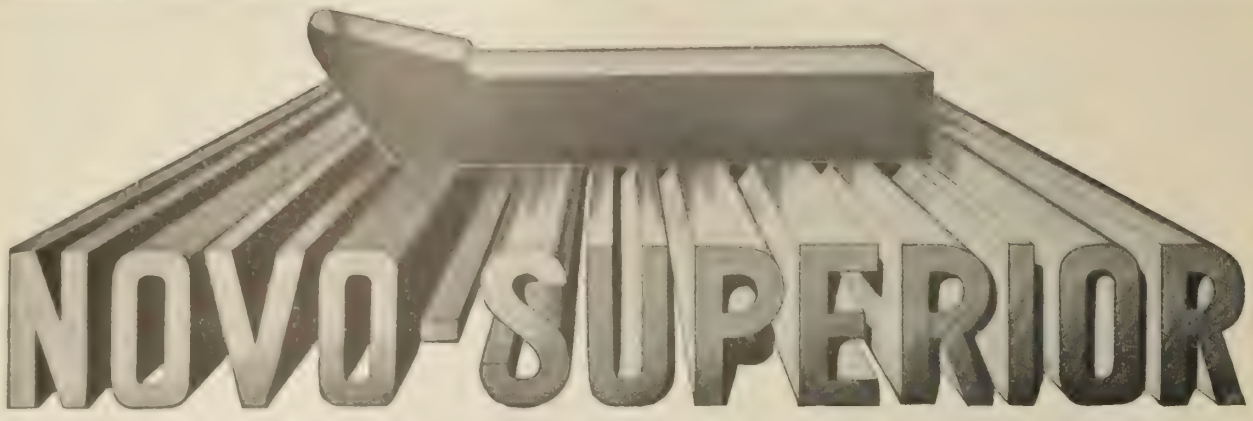
IN STOCK

—all these SHELBY SEAMLESS STEEL TUBES, drawn cold, through dies, like a piece of wire. Notice the smooth little round ones, the sturdy big ones; the thick and the thin ones, as well as the squares, rectangles, hexagons, ovals and odd shapes; then think how much time, how much temper, and how much REAL MONEY you could save by the use of this excellent material instead of machined steel, or cast iron, or brass.

Fifteen years ago you couldn't buy these tubes, because we didn't know how to make them. Now we will furnish you any size from ⅛ to 5½ inches outside diameter, and practically any thickness, from

Our Montreal or Toronto Stocks



and larger sizes up to 20 inches, on special orders. We have tubing with walls as thin as a business card, some so thick there's hardly room for a hole. We have tubing made from mild steel, and annealed for any particular purpose; also high carbon steel for bushings and special tensile requirements. We sell tubing from 3½ per cent. Nickel Steel for automobile construction. In a word, if there's *anything* you want in steel tubing, we have it, or can get it.

Look at the picture, which shows only a few of the sizes and shapes we carry, think how you could use Seamless Tubing in your work, then send for the story of how SHELBY TUBING is made. There are more possibilities for the use of this tubing than we could tell in a book. Write us—we will be glad to answer your questions.

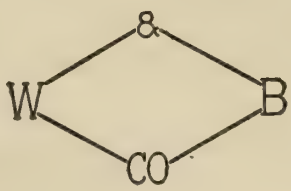
ACCURACY

To make Twist Drills that will do absolutely accurate work requires the greatest skill—years of experience and the most careful attention to each detail of manufacture.

To secure the greatest wearing quality requires the best of steel, tempered to exactly the correct degree of hardness. Not all Twist Drills attain these two essentials, but



"W & B-DIAMOND"

Twist Drills do and we ***guarantee*** them to be of ***highest quality*** and ***accurate to size.***

We make them from Carbon Steel and Vanadium High Speed Steel and carry the largest stock in Canada.

The "Hercules" High Speed Twist Drill shown on this page is one of our many types and is ***twisted*** while hot from Vanadium High Speed Steel.

The Geometric Threading Machine

equipped with one of our STANDARD DIE HEADS, is turning out a large amount of accurate work—work that cannot be done on the usual Screw Machine, and work that cannot be economically done in any other way.

The Die Head with which this Machine is regularly fitted has a range of cutting from ¼ inch to ¾ inch, the sizes obtainable being, ¼ inch, 5-16 inch, ⅜ inch, 7-16 inch, ½ inch, ⅝ inch and ¾ inch.

Where fine pitch threads are to be cut on larger diameters, the Machine can be fitted with a Die Head to take care of the work.

The chasers, from time to time, can be renewed at slight cost as they become worn.

Do not confuse our Machine with the usual run of Bolt Threading Machines.

PNEUMATIC TOOLS

The absolute safety and simplicity of transmitting compressed air, its wide range of profitable uses and the economies effected by its uses, give it an indisputable position of supremacy as a means of transmitting power for operating small portable tools.

Pneumatic tools are not delicate, complicated pieces of machinery, but positively simple, rugged little money savers, made to stand rough usage, yet maintain their efficiency.

In "Imperial" designs wearing parts are reduced to the reasonable limit of simplicity, and manufactured to give the greatest satisfaction.

No part of a plant equipment, representing the same investment, will do more to reduce labor costs, increase output and enlarge dividends than a good pneumatic tool equipment. We firmly believe that "Imperial" tools represent the very best sustained value, first costs, maintenance and operating costs being considered. They are thoroughly well designed, embody all practical up-to-date improvements and give very exceptional efficiencies. These features have won for "Imperial" tools their present favored position.

A BIG ENGINE

THE Engine, of which cut is shown here, was at the Glasgow Exposition and its bearings were lined with Magnolia Metal. We are informed that it was the only Engine that ran continuously during the Exposition without having to shut down because of hot boxes: whereas other large Engines at this Exposition, in the bearings of which the manufacturers used metals of their own make, had continual trouble. John Musgrave and Sons are among the greatest Engine builders of the world.

Globe Ironworks, Bolton, Lancashire.

Messrs. The Magnolia Metal Company, Limited.

Gentlemen,—In reply to your enquiry, we beg to inform you that we have used a very large amount of Magnolia for our bearings, and have found the same to give excellent results. We have fitted all our Electrical Engine bearings with this class of metal, including the Glasgow Engines of 5,000 I.H.P., the largest of which is 32 ins. diameter, 64 ins. long, and we have every confidence in recommending it for its splendid wearing and anti-friction qualities.

Yours truly,
(Signed) JOHN MUSGRAVE & SONS, Limited,
Walter M. Musgrave, Director.

"Simply Positive and Positi ely Simple"

Here's Why

When we tell you that you can save more power, you will have less trouble, you have a surer transmission using **Positive** Combined Friction and Jaw Clutches, than with any other type, we don't simply say, "There's a reason." We say, "Here's Why." And here is why.

You know that by being able to shut off at once machinery where idle, you save power. But, had you thought about the item of saving power when running---your biggest item. The **Positive** Clutch is a jaw clutch when running, yet it will couple a driving shaft at any speed into a driven shaft at rest against full load. You throw in the lever part way, and the frictions grip instantly until the driven shaft attains the speed of the driver; then the jaws engage and transmit the power, the frictions releasing. There is no wear, no slipping, no loss of power.

Positive Clutches always transmit all the power; they make good where others fail they cure transmission troubles. It's likely we've cured a case similar to yours. Aren't they worth investigating?

Interesting Data on Manufacturing Machine Tools*

By Luther D. Burlingame **

The Brown & Sharpe Co., Providence, R.I., Have Prepared Some Important Data of Interest to Men in Charge of Machine Tools. In the Accompanying Article the Author has Given Details of Feeds and Speeds Used in Milling, the Rate of Production, the Amount of Material Removed and the Power Required.

THE extensive set of special tools required to make a modern machine tool on a manufacturing basis and to attain the degree of accuracy required is indicated by the tool equipment for making the spiral-head swivel for a universal milling machine. The tools required for making it are listed below:

(a) Boring fixture and tools in cupboard.
(b) Counterbalance for grinding.
(c) Driver for turning.
(d) Counterbore for spindle rear-washer seat.
(e) Jig for drilling front-bushing screw holes.
(f) Reamer for index stop-pin hole.
(g) Taper reamer and test plug.
(h) Roughing and finishing taper reamer.
(i) Arbor for turning.
(j) Jig for drilling worm-shaft bushing stop screw hole.
(k) Jig for drilling oil and screw holes.

*Presented at joint meeting of American Society of Mechanical Engineers and Institution of Mechanical Engineers.

** Chief draftsman, Brown & Sharpe Manufacturing Company.

(l) Jig for finishing drilling-spindle stop pin hole.
(m) Milling cutter.
(n) Fixture for graduating.
(o) Fixture testing graduations.
(p) Test plug.
(q) Bushing for testing rear bearing.
(r) Device for testing.

Boring Fixture.

Among these tools the fixture for boring has been selected as typical of the extent of the equipment necessary for the production of such parts. Figs. 1 and 2 show this fixture in the cupboard made to store it when not in use, and in front is a spiral-head swivel for the manufacture of which the fixture was designed. The boring bars and cutting tools have their proper place in the top section of the cupboard, being so grouped that the tools for use in each position are together. The fixture itself is placed on a carriage in the lower part, this carriage being mounted on wheels which are guided on a track. When the front door is opened a section of track attached to it and matching the track in the cupboard provides that the carriage can be drawn out to a position where it can be readily lifted onto the boring mill. A hook on the end of each rail prevents the carriage from being run off onto the floor.

This boring fixture is of special interest in that it can be set to bore the swivel in three positions without removing it from the fixture. As set in Fig. 1 it is in position to bore holes A. After these are bored the swinging plate B is unclamped and the upper part of the fixture turned end for end so that other holes on the opposite side to the holes A can be bored. The swinging plate B is then turned at right angles to its former position and the upper part swung on trunnions provided so that lugs C can be clamped by bolts D upon the seat E, as shown in Fig. 2. This brings the fixture in position to face at F, and bore the hole for the spindle bearing, etc. The cover J, hinged to allow placing the work in the fixture, is clamped by a strap K which can be loosened and turned half way around to disengage it from the cover without removing the bolt. The lug

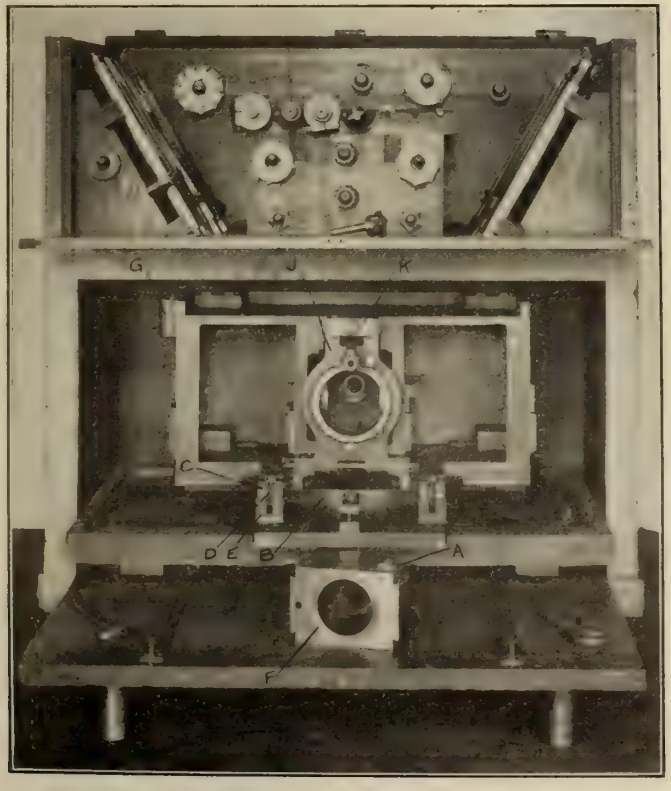

Fig. 1—Boring Fixture for Spiral Head Swivel.

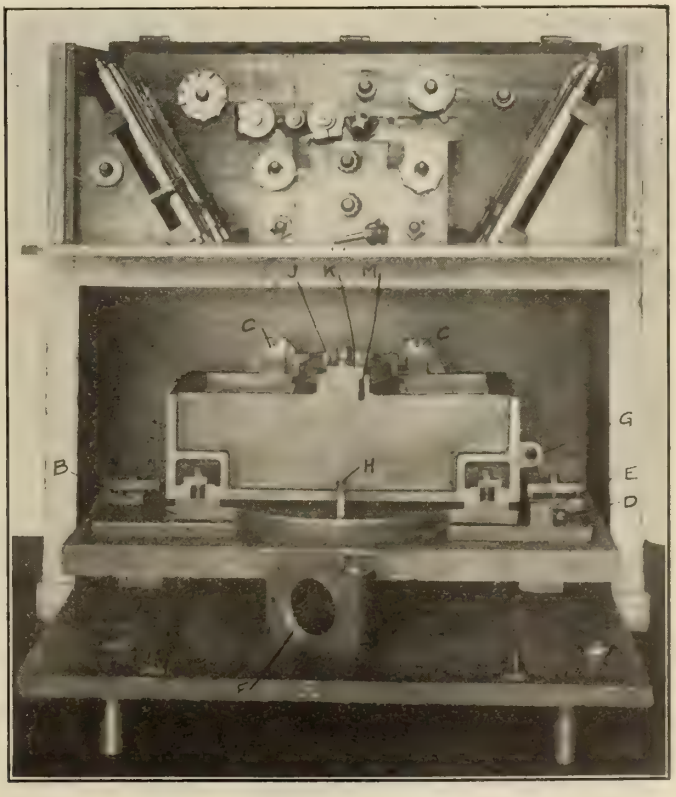

Fig. 2.—Boring Fixture for Spiral Head Swivel.

G is for the insertion of a bar to aid the workman in swiveling the fixture so that one man can operate it. The plug H fitting in a taper hole for each position insures the setting of the fixture so that all holes will be in perfect alignment. The slot M is for the insertion of a taper wedge which, coming against the face of the swivel locates as in the time of milling. In Fig. 4 is a data sheet for this operation, made out on a printed form such as is used by the Brown & Sharpe Mfg. Co. for such tests and the data given are for regular production under manufacturing conditions. It will be noticed that while the large cutters are of high-speed steel, the small cutters running at much lower surface speed are of ordinary carbon steel.

fixture is so made that the workman can easily replace the work so as to keep the machine going continuously. The cut on each piece is about 8 inches long, 4¼ inches wide at the widest part and about 1-16 inch deep.

Fig. 6 shows the style of inserted-tooth cutter used, this cutter, being of a design which avoids undue projection beyond the end of the spindle, allows the cutter to be easily removed, and also makes it possible to use the same cutter on machines with different sizes of spindles.

it in proper position before it is clamped in place. When not in use the cupboard is completely closed and locked.

Milling Top and Bottom of Milling Machine Tables.

Fig. 3 is an example of milling in which the top of one table and the bottom of another table of a universal milling machine are milled at one traverse of the machine, the milling being done on a Brown & Sharpe, No. 5-B heavy plain milling machine. At the completion of the cut one table is removed and the other one, which has been milled on the top only, is turned over so that the bottom may be milled [illegible] a rough casting is put in its place and the cut repeated. This illustrates economy in handling the work as well

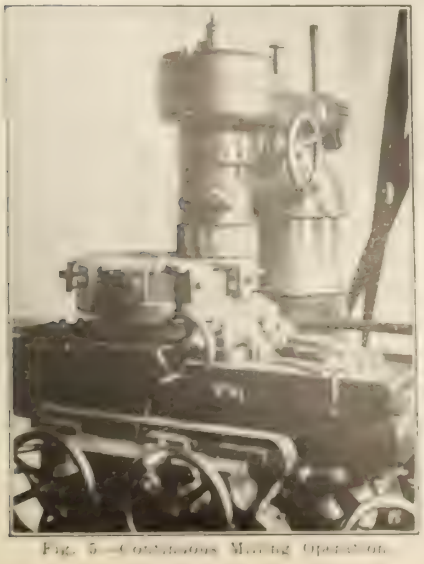

Fig. 5.—Continuous Milling Operation.

Example of Heavy Milling.

An example of heavy milling on a machine of the same size and type as used for the milling-machine tables is to be had in tests made on a steel block of 65,000 pounds tensile strength. Eighteen cubic inches of metal were removed per minute. The output of the motor was 21.05 horsepower, making 0.85 cubic inch removed per net horsepower. At no time during the test did the machine show signs of distress or appear to labor excessively, and the notable absence of vibration was emphasized in the following manner. A coin was placed upon its edge at one end of the table with its sides at right angles to the axis of the table, and on the opposite end a full glass of water was placed. The machine was then started and many cuts taken without overturning the coin or spilling any of the water.

A feature of note in connection with this test was the efficiency of the high-speed steel cutters employed. One gang removed 1,800 cubic inches of steel without having to be removed from the arbor for sharpening.

Continuous Milling Operation.

Fig. 5 gives an example of continuous milling on a Brown & Sharpe No. 5 vertical-spindle milling machine. In this case ten flat-iron bottoms were held in a special fixture on the circular milling attachment. The table makes one complete revolution in 4 minutes, thus finishing the surface of ten flat irons in 4 minutes, or 150 per hour. The

THE LANCASHIRE DYNAMO AND MOTOR CO.

The Lancashire Dynamo & Motor Co. have received the order for the complete motor equipment of the Wayagamack Pulp and Paper Co.'s mill at Three Rivers, P.Q., consisting of 44 motors of various sizes up to 400 h.p., together with the starting equipment for same. The motors will be for the most part of the squirrel cage induction type. The starting apparatus in a large number of cases will consist of totally enclosed auto transformer starters, with "in voltage and overload" releases, while in others, "star delta" totally enclosed starters will be provided. Eckstein, Heap & Co., Manchester, England, through their agents Chapman & Walker, Toronto, will supply the switch gear and main switchboard.

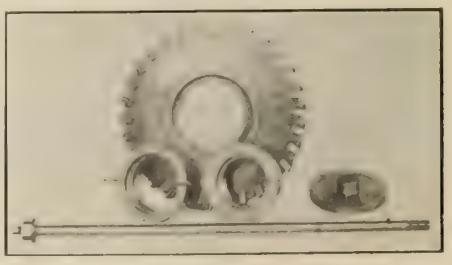

Fig. 6.—B. & S. Inserted Tooth Milling Cutter.

Sherardizing; a Modern Rust-Proofing Process

By Fred H. Moody, B.A.Sc.

The Hot Dipping and Electro-Galvanizing Processes of Galvanizing are More or Less Familiar to All; But the World Moves Apace, and Newer and Better Methods of Rust Proofing are Being Invented, Important Among These Being Sherardizing, Which is a System of Dry Galvanizing. By it, Machine Cut Threads, for Example, can be Protected, Leaving the Surface as Perfect as Before Tratment. Such a Process is Worth Investigating, and With That Object in View, This Article Gives a Description of What it is, How it is Done, its Theory, and Examples of its Varied Uses.

From the earliest times when iron and steel came into extensive use, the trouble of rusting, that is the oxidizing of the surface, has always been one of the principal troubles to contend with. Engineers at all times have attempted to produce non-rusting surfaces, and the results of these attempts have been the production of many more or less effective protective means. Like many another great discovery sherardizing was purely accidental, as shall be explained later.

Of the many effective coatings employed to stop corrosion, zinc has proved to be one of the best, being itself but slightly amenable to ordinary climatic conditions. Zinc coatings as generally employed are in the form of the usual galvanized surface, that is a thin film or envelope of the metal, covering the surface to be protected in a more or less perfect manner; the protectant, zinc, however, merely forms a coating, or separate jacket, in no sense an integral part of the article itself. This does not apply to the sherardized surface.

Previous to this method of zinc coating iron and steel to be discussed, there were only two means of so doing, the hot dipping and the electric process of galvanizing.

In the hot process, the articles to be galvanized are dipped into molten zinc which melts at a temperature of 786 deg. F., but the temperature in the pot must be kept much higher than this to counteract the cooling effect of the newly immersed articles. This necessitates a temperature in many cases 100 degrees higher than the melting point. This heats the articles to be coated, unduly, so that when immersed in cold water, which is necessitated by the fact that otherwise the surface zinc would oxidize, the articles have a tendency to warp, especially in work that is irregular in form. The deterioration resulting in the iron after this process can be traced directly to this cause; the metal is made coarse and brittle.

The result of capillary attraction of the molten metal, tends to fill up small crevices, and, in the case of bolts and nuts, destroys the form of thread. Recutting and retapping would remove these defects, but, at the same time, would not remove the zinc surface uniformly, and leaving a surface partly unprotected by zinc. Thus the object of galvanizing would be undone as the surface would be left unprotected in spots, these spots gradually spreading, through corrosion. Attempts have been made by some to first dip the bolt stock, and then roll the threads afterwards, but this has the defect of breaking the protecting surface during the rolling process.

The principal difficulty with electro-galvanizing is the inability to coat irregular surfaces uniformly, as the amount deposited at a point varies inversely as

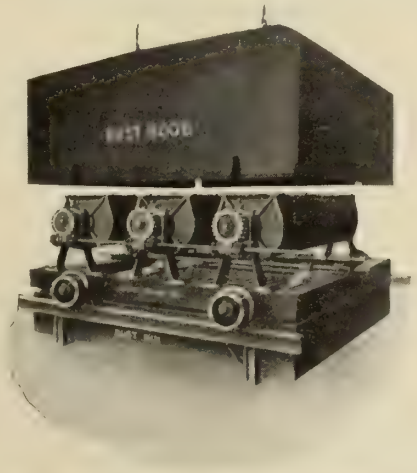

Fig. 1.—Sherardizing Machine Showing Dust Hood.

the distance between the anode and cathode. This objection does not occur in objects that can be arranged at a uniform distance so that the coating may be evenly spread. The electro-galvanizing differs from the hot process in that no deterioration of the metal occurs; but, from the non-uniformity of coating and the expense of operating such a plant, the process is not in very general use. The resulting surface is also soft and spongy.

As before mentioned, with both these processes, the coating is purely superficial, being glued on, so to speak, and not forming an integral part with the work to be protected. If for any reason the surface is not carefully cleansed from scale, grease, acid, etc., the protecting zinc will form a blister over the foreign substance, in the hot dip case, and will deposit nothing in the electric process, so that this foreign substance leaves an opening for attacking substances to corrode the article.

If two sheets of copper and zinc be placed in intimate contact for several weeks, it will be found, upon removal that both surfaces will have a covering film of brass, from the union of the copper with the zinc plate in one case, and the zinc with the copper plate in the other. This goes to prove that heat is not always an essential for the formation of an alloy, and this contention has been proved by the investigation of different eminent scientists. The same investigators have proved that alloying at low temperature tends to prevent entectics, when particles of one metal are merely suspended in the other. The failure of babbit metals may in many cases be attributed to this cause.

The discovery of the sherardizing process is due to Sherard Cowper-Coles, the noted British electro-metallurgist, who, while engaged in a series of experiments in connection with the annealing of iron discovered that metals in a fine state of division, i.e., in the form of a fine powder, when raised to a certain temperature which was several hundred degrees below the actual melting temperature of that metal, when in contact with a solid metal, volatilize, and gives off vapors, which condense on the solid metal immersed in the powdered metal. This has been applied to the coating of iron and steel with zinc by this process.

The zinc powder used is the ordinary zinc dust of commerce, not zinc oxide; and it is obtained in the process of distilling zinc from its ores. It is commonly called "blue powder," and is the dust which sublimates in the flues of the smelter, and amounts to from five to ten per cent. of the yield of spelter. In this powder are beads of pure zinc and traces of cadmium, lead, and iron, but a small amount of free oxide, besides it is mostly composed of impalpable particles of blue grey powder from 1-40,000 to 1-50,000 of an inch in diameter.

The zinc dust particles are zinc in a very unstable state, due to the sudden

cooling to which each minute particle is subjected. The chilled surface of each of these spherical particles is oxidized, which bears an important part in the theory of zinc dust action. Inside the molecules of the metal are packed without any regular order, and they are constantly striving to rearrange themselves in more comfortable order, which cannot be done without bursting the chilled shell in which they are confined,

Fig. 2.—An English Sherardizing Furnace, Showing Drum Containing 2,800 lbs. Bolts, the total weight being 6,600 lbs.

and the reaction of this catastrophe results in vaporization. Hence, at a temperature far below that at which the metal itself would be volatilized, the zinc dust is converted into a vapor of zinc with some oxide. The temperature at which this zinc dust vaporizes is around 400 deg. F., a temperature at which metallic zinc is very brittle.

Articles to be sherardized are first cleaned in any of the usual ways such as pickling or sand-blasting, the extent of the cleaning largely depending on the work to be done. In contradistinction to the hot or electric method, the surface does not of necessity need to be freed from oil, as the latter has been found to have no detrimental effect.

The articles are placed inside iron [illegible] drums along with sufficient zinc dust to completely cover them. The drums are then closed up with dust-[illegible] and gradually heated up, being meanwhile slowly revolved or oscillated, as in [illegible] order to insure good contact between the dust and the articles. It is practically impossible to break articles through too rapid heating, as the intervening dust acts as a poor conductor of the heat, taking considerable time to transmit.

After the necessary length of time in the oven to do the sherardizing, the drums are withdrawn, and allowed to cool slowly before opening, the poor conductivity of the dust acting in a manner similar to the previous instance, the articles cooling so slowly that warping and breakages are reduced to a minimum.

Experience has shown that the maximum temperature for sherardizing never exceeds 750 deg. F., so that the inherent qualities of the articles are never injured; highly tempered and fragile articles are handled at a much lower temperature, the maximum temperature of the furnace never exceeding 750 deg. F., which is 36 degrees lower than the melting point. Owing to the poor conductivity of the metallic powder, the maximum temperature in the drum where the articles are, is much less, and is said to never exceed 700 deg. F.

On opening the drum, the articles contained are found to be completely covered with an even homogeneous coating of metallic zinc. The threads of fine cut bolts and nuts are found to be as perfect as before the operation, the bolt and nut fitting perfectly, and no part is left unprotected. Steel gauze comes out perfectly coated and without a single hole having been stopped up, and any scratch on the surface before treatment, comes out clean and sharp to the vision. Still more wonderful, a close coiled spring will come out uninjured, and not only coated inside and outside of the coil, but also rust-proof between each individual spiral as well, notwithstanding the fact that the spirals had been in close and hard contact with each other during the process of sherardizing. Scales graduated to the hundredth part of an inch, come out perfectly clear and distinct.

A microscopic examination of a cross-section of a sherardized surface shows the nature of the coating. It is found to be literally rooted to the article under treatment. At the top is pure zinc, followed by zinc-iron alloy, succeeded by an iron-zinc alloy, merging into the iron of the article. All these merge into each other in such a way as to make a homogeneous substance, and not a mere surface filament, merely fastened on.

The whole question of protecting iron or steel from rusting by means of a coating of zinc, is an electrical one and is based on exactly the same principles as those found in an electric battery. The iron and zinc form the negative and positive elements of an electric couple, while the atmosphere, always more or less damp, acts as the exciting medium. So long, therefore, as the iron is more or less covered with zinc, it corrodes but little as it is saved from corrosion at the positive zinc elements' expense, which is oxidized by the damp atmosphere. In addition to this principle, though it may be considered as part of it, is the fact that the oxidized zinc is precipitated on the surface of the zinc proper, in the form of more or less insoluble salts, which mechanically polarize all further action until this deposit is removed.

The alloy in itself affords a great protection, for experiments show, that the covering may be eaten down through the zinc to the alloy, and there indefinitely retarded by the resisting powers of the alloy.

The sherardizing process proves invaluable in detecting flaws in work, for from the fact that there is no capillary attraction to fill up crevices, causing cracks, invisible before treatment, to become apparent, thus leading to the discarding of the damaged piece.

At first sight it may appear strange that the drum itself should not be coated; this is due to its higher temperature; it emphasizes the fact that condensation occurs like that of atmospheric moisture on a cold water pipe. As before pointed out, the furnace temperature, which is the temperature of the shell, is at least 50 degrees higher than in the interior.

A sherardized surface may be readily buffed, giving a similar finish to nickel plating, being bluish like silver, and of a higher reflecting power, the difference being quite apparent to the naked eye.

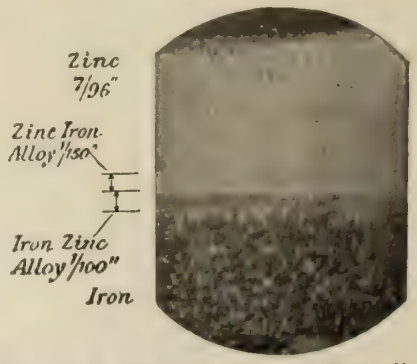

Fig. 3.—Microphotograph of Sherardized Surface Magnified, 12 Diameters.

The ready manner in which a sherardized surface will take on a finish has been employed in a new line recently, that is, in damascening, as formerly done consisted in chasing a design upon the metallic foundation of the object to be decorated, and then filling the incisions with fine wire or strips of other metal, by means of a special tool, the whole being finally smoothed and polished. Literally, the pieces were dovetailed in so as to secure permanent set. Sherardizing opens a new method of doing this, for by first taking the object to be decorated be it copper, iron, etc., and covering it with a stopping-off composition, and engraving the design in this composition, if the article be then

Fig. 4.—Copper Tray, stopped-off ready to be damascened by the Sherardizing Process.

sherardized, a covering of zinc is added to the stopped off places, which on a copper article forms a brass finish. This forms a new method of inlaying brass on copper. Vessels of all kinds can be treated this way, the cut showing an example.

The rights to grant authority to sherardize in Canada, are held by Factory Products, Ltd., Toronto, who have purchased outright the Canadian patents.

RAPID TURNING PREPARATORY TO GRINDING.

By G. E. Brownell *

IN the production of cylindrical machine parts by means of the lathe and grinding machine, too little importance is usually attached to the lathe operations preparatory to grinding.

There seems to be an instinct to accuracy, born of long experience in using the engine lathe as a finishing tool, that prompts the average lathe hand to use fine feeds and make nice clean cuts and a smooth surface on the work he is truing, regardless of whether he is making a finish cut on a piece of work to be filed and polished, or rough turning preparatory to grinding.

Rough turning preparatory to grinding means using the fastest feeds and speeds consistent with the power available in the lathe in which the work is being done. It cannot mean clean cuts and smooth surfaces because no high speed steel tool, working at its full cutting capacity, will cut smooth after a few minutes' use.

* Norton Grinding Co., Worcester, Mass.

If we examine a high speed steel tool that has been used for a half hour roughing shafts, in a powerful lathe, we find that the cutting edge is not sharp; but, on the contrary, presents a dull or slightly rounded appearance, and has small particles of the steel it has been cutting adhering to it.

A high speed steel tool in this condition has been known to stand up all day roughing .50 carbon hard, open hearth steel motor shafts, at a cutting speed of 65 ft. per minute and $\frac{1}{8}$" feed per revolution, removing from $\frac{1}{4}$" to $\frac{1}{2}$" stock from the diameter in one cut.

The number of cuts required to reduce the diameter to grinding size will depend somewhat on the lathe in use. It may mean three cuts in some cases, but if powerful lathes are used, it is possible to rough turn to grinding size in a single cut.

Cross feeds should be used except in cases where very deep cuts are taken. I recall an instance where a bar of steel $5\frac{1}{2}$" diameter was reduced to $3\frac{7}{8}$" plus 3-64" for grinding in one cut, using 1-32" feed per revolution.

It was my good fortune a few years ago to be in the employ of a large electric motor manufacturing company while they were changing their methods of manufacture from turning, filing and polishing, to turning and grinding. It had been their practice to rough turn the motor shafts to within $\frac{1}{8}$" or 3-16" of finished diameter, low priced help being used for this operation. The shafts were then taken to the engine lathe where two cuts were taken over them before filing and polishing. After installing grinding machines, this practice was not changed except that the last, or sizing cut, was taken in the grinding machine instead of the engine lathe.

After a varied experience, parts of which were pleasant and other parts not quite so pleasant, we realized that the saving accomplished by grinding the amount of stock usually left for the final, or finishing cut, in the engine lathe did not represent the total saving in cost of production that was possible, could we change our method of turning before grinding. Some of us thought that it was possible to rough turn the shafts to grinding size in a single cut.

High speed steel tools were not in general use at that time, but a few were in the shop and were considered as special tools, and could only be taken from the tool supply department by presenting a requisition from the foreman. Some of these high speed steel tools were secured and a number of shafts were rough turned experimentally. Different methods were used to prepare them for grinding: Some were turned with a coarse feed; two, and in some cases three, cuts were necessary to reduce them to grinding size, i.e., 1-32" to 3-64" over finished size; others were turned with a fine feed, and at a faster cutting speed, reducing them to within 1-64" to .020" of finished diameter, with one cut.

Careful note was made of comparison in time occupied in rough turning. A comparison of time occupied in grinding was also made. The results were so favorable that it was decided that all shafts to be ground should be turned to grinding size in the roughing lathes, using as coarse feeds as the lathes would carry.

A little more experience in rough turning showed us that the high speed steel tools would stand to take heavier cuts than the lathes would pull. Heavier and more powerful lathes were purchased and proved very satisfactory. The result was a remarkable increase in the rate of production.

STRAIN ON HOISTING ROPE DUE TO SLACK.

Experiments made by placing a dynamometer between the rope and the cage in a hoisting plant showed conclusively the bad effects of starting the load with a jerk due to a slack rope. When there was $2\frac{1}{2}$ inches of slack, the stress on the rope was 39 per cent. greater than if the load were lifted slowly and gently. With 3 inches of slack the stress was 65 per cent. greater than if lifted slowly and gently. With a slack of 6 inches, the stress was 122 per cent., or more than double, and with 12 inches slack the stress on the rope was three times as great as when starting slowly with a taut rope. Such sudden stresses on hoisting ropes necessarily cause deterioration in the strands, which eventually result in breakage, even sudden breakage of the rope. The jerk can be greatly reduced by care on the part of the hoisting engineer, and the insertion of a good spring connection between the cage and the rope.—Mines and Minerals.

LARGEST ELECTRIC MOTOR.

The largest electric motor in the world is now being made in Stafford, England. It will have a capacity of 10,000 horse-power and will weigh nearly 200 tons. A 920 volt current will supply it. The commutator will be 12 feet in diameter. The motor will be used for driving a steel rolling mill.

Geometric Chaser Grinder.—A neat 12-page booklet issued by the Geometric Tool Co., New Haven, Conn., describes this grinder, and several illustrations show it in use, and give an idea of its applicability. Short talks on the frequency with which dies should be ground, etc., are given.

The Evolution of the Centrifugal Filtration Plant Pump

By K. Campbell

The John Inglis Co., Toronto, Recently Completed a Centrifugal Pump for the Toronto Filtration Beds. The Machining of the Main Body of the Pump Presented a Problem Which Was Successfully Solved by the Superintendent. A Complete Description of the Machining and the Pump Construction is Given in This Article.

TWO centrifugal pumps were recently completed for the Toronto filtration plant by the John Inglis Co., Toronto. These were a 12 in. drainage pump and a 48 in. pump for filtration purposes. The latter is designed for 45,000 Imperial gallons and a 9 ft. head. Owing to pressure of work requiring the full capacity of their foundry, the two castings of the body weighing 14 and 8 tons respectively or a total of 22 tons, were made by the Berg Machinery Co., Toronto.

Fig. 1.—Core for one of the pump castings, Foundry of Berg Machinery Co., Toronto.

Fig. 1 shows a corner of the foundry of the Berg Machinery Co. The core for the smaller of the two castings is held suspended over the mold by a jib crane. Fig. 2 shows the large casting in the yard of the Berg Machinery Co. as it came from the mold. The casting was then cleaned for delivery, the completed casting being shown in Fig. 3.

Fig. 2.—Large Centrifugal Pump [illegible] Berg Machinery Co., Toronto, as it [illegible] mold.

Fig. 4.—The two large castings of the Centrifugal Pump in position, at the works of the John Inglis Co., Toronto.

Machining.

The machining was done in the machine shop of the John Inglis Co. The faces for the joints were planed, one

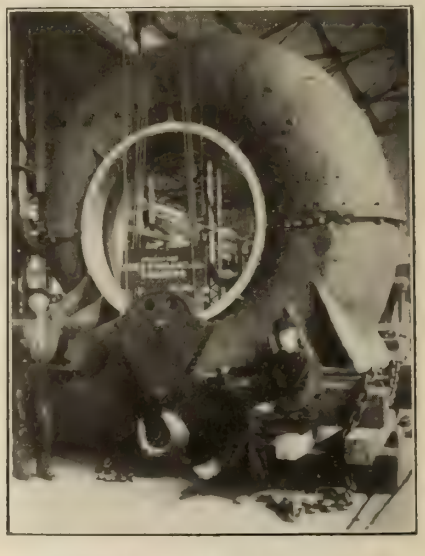

Fig. 5. Giving an idea of the size of the Centrifugal Pump.

half at a time. They were then bolted together for boring. The large boring mill has a capacity of 10 to 16 ft., while the casting was 19 ft. 6 ins. to the outside corner. The pump could not revolve and bar revolved with table. Thus, instead of the work revolving, it remained stationary, while the boring bar revolved, a casting bolted to the face plate driving the boring bar.

Fig. 3.—The finished casting in the yard of the Berg Machinery Co., Toronto, ready for delivery to the John Inglis Co., Toronto.

under the housings nor be machined in the regular way.

The pump was fastened on the outside foundation plate, one end of boring bar being attached to table of boring mill and other to cross-head of machine. This bar had a screwed feed travelling head

The bearing faces were planed at right angles to the face bored out, referred to in the previous paragraph. The outlet was machined last. Fig. 4 shows the two large castings complete after machining. The comparative size of the pump is shown in Fig. 5.

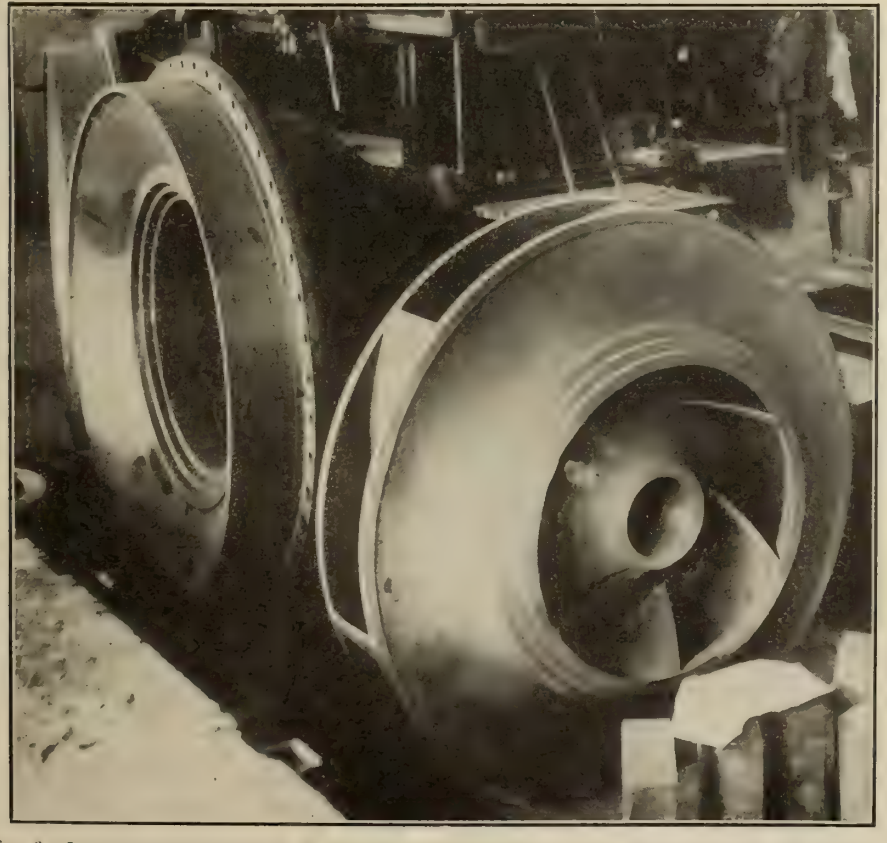

Fig. 6.—Impeller and Bearings of the Centrifugal Pump after machining, in the works of the John Inglis Co., Toronto.

The impeller and two bearings are shown in Fig. 6. The impeller is 66 ins. in diameter and weighs two tons. Each bearing was made in two parts, a complete elbow or bearing weighing three tons. The joints of the elbows were planed, and the two parts bolted together. Each elbow was then bored and faced in the boring mill.

The complete pump with all parts assembled is shown in Fig. 7. There are two intakes of 37 ins. each and an outlet of 48 ins. The pump complete occupies a floor space of 7x12 ft. and is 10 ft. high.

The pump is driven by the tandem compund condensing steam engine. The diameter of the high pressure cylinder is 13 ins., low pressure 27 ins., with a stroke of 36 ins. and r.p.m. 104. The floor space of the engine is 9x28 feet.

THE WESTERN BRIDGE AND EQUIPMENT CO.

Owing to increased business and the want of land adjacent to their present shops for extension purposes, the Western Bridge and Equipment Co., of Chatham, Ont., have started a new shop building, 82 by 225 feet on part of a 7 acre lot given by the City of Chatham. The land is located between the G.T.R. and C.P.R. The building will cost $10,500, and will have overhead traveling cranes throughout its entire

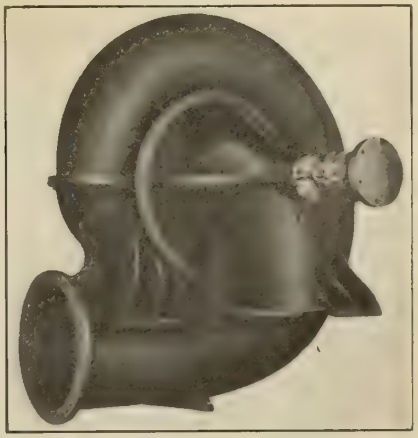

Fig 7.—Centrifugal Pump, Built by the John Inglis Co., Toronto.

length. The general equipment will be that of an up-to-date bridge and structural steel works. A charter has been applied for, under the name of the Chatham Bridge Co. Ltd., with capital of $200,000. A large part of this stock has been already placed, and purchase made of some of the tool equipment from the A. R. Williams Co., Toronto. A further tool purchase to the amount of $10,000 is projected in the near future. The provisional directors are: A. E. Drew, W. P. Drew, T. A. Drew, T. C. Martin and A. Lanigan, all of Chatham, Ont.

Mechanical Drawing and Sketching for Machinists*

By B. P.

A Series of Progressive Lessons Designed to Familiarize Engineers With the Use of the Apparatus Necessary to Make Simple Drawings, to Encourage Them to Realize How Important a Factor it is of Their Equipment, as Well as Being a Profitable Pastime.

The text and illustrations constituting the fifth article of our course form an introduction to the drawing of straight lines with curve or part circle connection at their extremities; the combination of which goes to make a detail of mechanical utility. Fig. 1 shews two steel plates ¾ inch thick, butt-jointed by means of a 4½x3½x¾ inch tee iron, single riveted to each plate by rivets 13-16 inch driven diameter. The rivets are spaced midway between the outside of tee iron web and outside of flange on same side. The rivet head diameter is 1.6 times the rivet body diameter and its thickness at centre .8 of the body diameter. The rivet holes should be slightly countersunk on the head faces as shown; this being done with writing pencil or pen freehand.

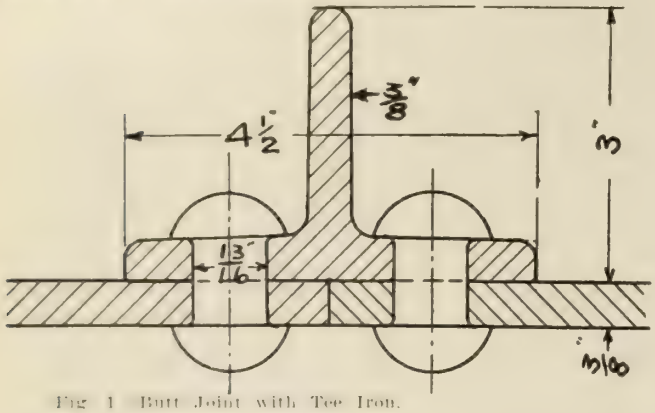

Fig. 1.—Butt Joint with Tee Iron.

In making a full size pencil drawing of this joint, begin by drawing horizontal lines representing the plate thickness, making the left hand extremities of these lines begin one inch from that edge of your paper and four inches down from the top edge of same, to the upper thickness line. Make these plate thickness lines about 6½ inches long and in the middle of this length, draw a vertical line by means of your tee and set squares to represent the butt or joint of the two plates. At this joint or butt, continue a faint vertical construction line, on each side of which, mark off the half thickness of tee iron and draw vertical lines just over 3 inches from top of plates.

As the tee iron is 3 inches deep, draw with your compass?s a s?mi-circle whose crown reaches the 3-inch mark, and whose radius is 3-16 inch. The base flanges of the tee iron have a mean thickness of ⅜ inch, and are at the outer edge 1-32 less than this. The inner edge where connection is made with the web will have a thickness 1-32 inch in excess of the mean. Each lower flange will therefore have a slight downward taper on upper face from inner to outer edge. The radii of outer and inner ends of upper face of tee iron flange is 3-16 inch, and should be drawn with the compasses.

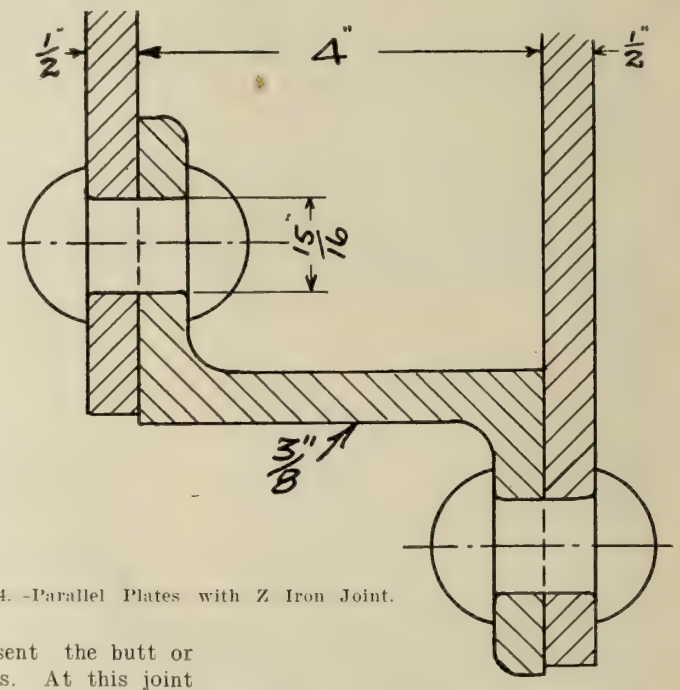

Fig. 4.—Parallel Plates with Z Iron Joint.

It will be noted that Fig. 1 represents the connection of two plates of equal thickness and in the same straight line. Fig. 2 shows two plates of equal length and thickness, parallel to each other, joined together by means of a channel

---

* Part of a Course of an Instruction Course. A [illegible] will be given each month.

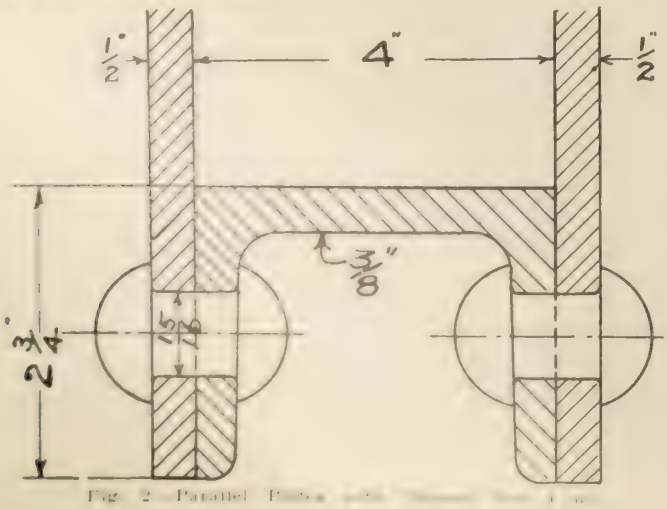

Fig. 2.—Parallel Plates [illegible]

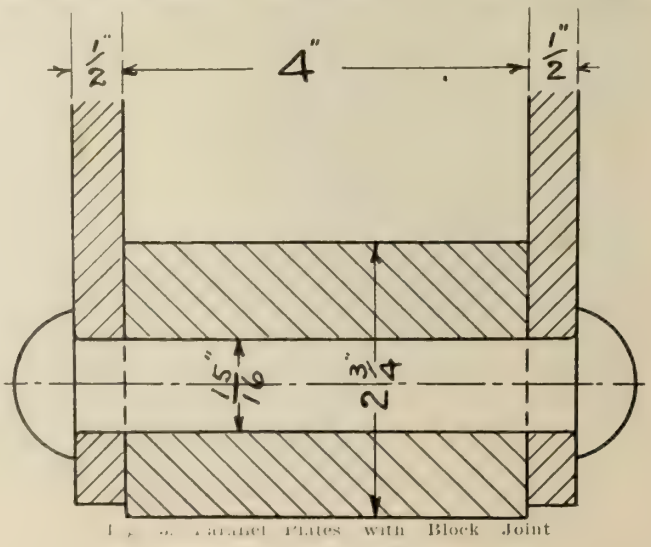

Fig. [illegible].—Parallel Plates with Block Joint

iron, while Fig. 3 represents like plate conditions with a solid piece or block joint. Fig. 4 represents two parallel plates of unequal length joined together by an Z. bar. All of these figures should be drawn full size and carry the same rivet head proportions to diameter as Fig. 1. The remarks on radii and position of rivets apply also as in Fig. 1.

The sectional shading shown on the sketches does not correspond with the illustration and instruction given in our previous article. You will, however, make it to correspond.

Instruction in making these drawings in pencil is more or less superfluous, they being to a large extent self explanatory. It will not be out of place, however, to say a few words on inking-in your drawing. Having completed the pencil work, the first thing to attend to in inking, is that of the radii. You will therefore put in the flange and web radii in each case, also the rivet heads, head and body freehand fillets. Having done this it is simply a case of drawing the straight lines with your squares and drawing pen to join up. In inking, begin at the top of your sheet and work down for horizontal lines, and at the left hand side of the sheet for vertical lines, working to the right.

The G.T.R. Car Shops, London, Ont., "Welfare" Dept.

By Halyard

In the March issue of "Canadian Machinery," the writer gave a brief outline description of the McClary Mfg. Co.'s "Welfare" scheme and its operation. The present article is written to show what one of our large railroad systems is doing along similar lines with the co-operation of its employes, in the same city, and forms one more link in the chain of evidence, which goes to prove the efficacy of such schemes, in securing and retaining satisfactory relationship between capital and labor.

THE G.T.R. car shops, London, Ont., exist largely for the repair and upkeep of freight and passenger cars, and are a centre or headquarters for this purpose in a wide and important section. A striking feature of the yards, buildings and equipment, is the cleanliness, tidiness and order prevailing; conditions which of themselves conduce to "welfare" and self-respect of employes, as well as hearty effort in the accomplishment of their work. The various shops are well lighted and ventilated, and have thoroughly modern lavatory accommodation whereby the employes at the close of the day's work may, if they so choose, erase all trace of the effects of the hours of toil, and leave for their homes feeling in good spirits, clean and satisfied.

Library and Dining Room.

Provision has been made for leisure as well as for working hours, and the wants of the inner man are also catered for. The library and reading room, Fig. 1, forms a section of a long one-storey brick building, of which the general offices, store rooms, dining room, fire station, paint shop, etc., also form a part.

The library leading dimensions are 60 by 30 feet; it contains 5,000 volumes of wholesome literature covering every field, and is supplied with the leading Canadian and American daily papers, as well as the brightest and best weekly and monthly magazines of both these countries and the Old Country. On either side and ends of the long central table are to be found revolving easy chairs for reading, and in addition to the papers and magazines already referred to, we noted a globe of the world, several sets of stereopticon views, etc. Concerts and entertainments for employes and their friends are held here, seating accommodation being provided for 300 people. The membership fee is 50 cents per annum, and the enrolment shows a total of 180. An annual concert in winter and excursion in summer provide means from their successful and profitable carrying out, whereby additions of books by purchase, are made to the library.

The walls are handsomely decorated, and are ornamented with pictures and groups of railroad officials and equipment, busts, etc. The interior woodwork is of southern pine in natural finish; with furniture of oak and oak-grained hardwood.

Drawing classes in winter for employes, having an enrollment of 50 and an average attendance of 35, form another attractive feature of the "welfare" department. Instruction in this course is given two nights per week in the library.

The dining room is the same size as the library and has attached to it a cooking and wash-up room 12 by 30 feet, Fig. 2. Meals are served at moderate rates and are largely taken advantage of by the men at the noon hour.

A committee of management looks after the library and dining room de-

Fig. 1.—Library and Reading Room, G.T.R. Car Shops, London, Ont.

partments, and is elected annually from among the members. Every Friday at noon the London Y.M.C.A. hold a meeting, at which one speaker and one singer are present for the instruction and entertainment of the audience, which is usually large.

Mr. Treleaven, the master car builder, and the other leading officials enter heartily into this "welfare" work, yet while naturally giving it the best of their time and effort, do not neglect National or Imperial interests when opportunity presents, as evidenced by the erection of a new and tall flag pole with a model railroad car on top and saluting of a new flag with due ceremony, followed by an employes' recreation field day, on the occasion of the coronation of our late King.

ECONOMY OF EFFICIENT FIRE PROTECTION.

The annual fire waste in America is appalling, exceeding $100,000,000 by conservative estimate. This estimate is for the actual loss of property, there being no data, of course, for the loss of wages and profits, and indirect business losses generally. The fire insurance companies, as a matter of good business policy, have brought about many reforms in factory construction designed to greatly reduce the fire risk. The growing use of concrete is another factor that should tend to reduce the proportional loss, though it is doubtful if the aggregate fire waste will show perceptible diminution in the next twenty years, or until a large part of the present wooden structures have burned or been torn down.

Among the means for preventing destructive fires, the sprinkler system, which originated in the needs of woodworking mills, is the chief. There is little chance for a fire started in a building equipped with sprinklers as prescribed by standard specification, to become a conflagration. The moment the temperature of the air surrounding the sprinkler head reaches or exceeds 160 degrees F., the fusible links melt, and the flow of water automatically starts. If the fire spreads, more sprinklers go into action and unless the conditions are enormous the flames are promptly extinguished.

The experience of a well-known manufacturing [illegible] of the Northwest is a good illustration of what this system means in saving insurance premiums. For several years the plant consisted of wooden buildings and being outside the city fire protection limit, the insurance rate was high, the premium being about $3,000 annually. The new building of semi-fireproof construction has been built and equipped with the sprinkler system throughout. The annual premium on twenty per cent. more insurance is only about $200. Counting ten per cent. interest and depreciation on the investment in the protection system, there still remains a large annual saving, and besides that the greatly added security of the business, which has required years of hard work to build up.—Machinery.

SHOP CHANGES DUE TO THE STEEL CAR.

The Railway Age-Gazette refers to the shop side of the steel car era as follows: "The introduction of the steel car in both passenger and freight service is rapidly transforming the equipment of most railroads and gradually changing the character of the car shops and making its impress upon the car department generally. The shops are becoming iron working shops with punches, shears and riveters, and the repair men are no longer carpenters and cabinet makers, but sheet metal workers and blacksmiths. The design of the steel car is an engineering problem, and most of the work can be handled better by the machinist or other iron worker than by the old-time car builder or woodworker. It is a remarkable fact, however, that the cabinet maker in the shops of the large passenger car builders has so adapted himself to the fitting of steel sheets, moldings and trimmings that his work is more rapid and accurate than the regular sheet metal workers."

Fig. 2. Dining Room, G.T.R. Car Shops, London, Ont.

EDITORIAL STAFF ADDITION.

A change in the personnel of our editorial staff made necessary the appointment of a new associate editor, and we have been fortunate in securing the services of Mr. J. H. Williams, late assistant shop engineer, C. P. R. Angus shops, Montreal, to fill the position. Mr. Williams brings a weight of practical machine shop methods and practice to the service of our trade publications, particularly Canadian Machinery, and our readers may rest assured of their interests and requirements being carefully looked after in the future.

Mr. Williams served his apprenticeship with the North British Locomotive Co., Glasgow, a corporation employing 8,000 men, and turning out 700 locomotives per year. He worked as draftsman with J. H. Carruthers & Co., Polenadie Pump Works, with Watson, Laidlaw & Co., makers or hydro-extractors, centrifugals and sugar machinery, and with Kerr, Stuart & Co., Stoke-on-Trent, England, as leading draftsman. He came to Canada four years ago, and has been employed at the C.P.R. Angus shops, Montreal, until joining our staff, first as draftsman and then as assistant shop engineer. His technical training was received at the Glasgow and West of Scotland Technical College, an institution of world-wide fame in the matter of staff, equipment and quality of instruction imparted.

Boiler Design, Construction, Operation, Repairing and Inspection *

By H. S. Jeffery

Repairing Tubular Boilers.

(17) The repairing of a tubular boiler is a simple matter—a very simple matter. The chief consideration is to make the repair so as to weaken the boiler as

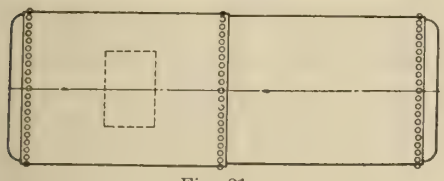

Fig. 21.

little as possible, and to apply the patch in such a manner so it will serve as near as possible the part it replaces.

The applying a patch to any boiler in such a manner as will necessitate the work being done over within a short time, which usually means more extensive repairing in the second instance, is due to two reasons, and they are: Haste and incompetency on the part of those making the repairs. The incompetency in this instance, means lack of knowledge of boiler reconstruction, or in other words the repairing of a boiler in a practical manner.

Take for instance a tubular boiler. Now, if the shell sheet is to be patched, the hole in it should never be cut as shown in Fig. 21; it should be cut in the manner indicated in Fig. 22. The sharp corners of the hole, Fig. 21, will permit under the panting or the breathing of the boiler the shell plate to crack from the corner into the solid plate Also, since the patch would be applied with a single riveted joint, the cutting of the hole in the shell plate, as shown in Fig. 21, would place in the longitudinal plane a single riveted lap joint, which, of course, would have an efficiency greatly below the efficiency of all other joints in the same plane.

The manner of installing the hole in a shell plate, as shown in Fig. 22, over-

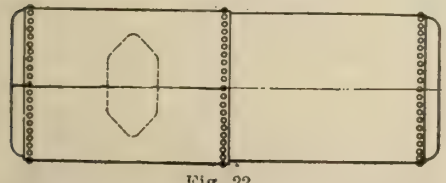

Fig. 22.

comes cracks into the solid plate as previously mentioned. In addition, it will be noted, in Fig. 22, that there is no single riveted lap joint in the longitudinal plane. The hole in the shell plate, Fig. 22, permits a single riveted lap joint in the transverse plane, and the rivets should be so pitched so the efficiency of the joint of the patch is the same as the girth seam of the boiler. It will be noted that a portion of the single riveted lap joint would be diagonal, which is the best arrangement that can be made, and one which is to be preferred to the single riveted lap joint in the longitudinal plane.

Inside and Outside Patches.

(18) A subject which boilermakers do not altogether agree upon is the method of applying a patch to the bottom of a tubular boiler. Some boilermakers believe in applying a patch inside the

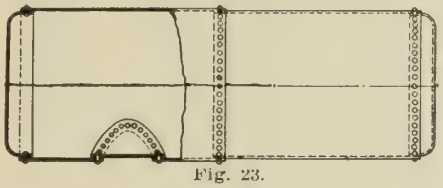

Fig. 23.

boiler as shown in Fig. 23, while others believe in applying the patch on the outside of the boiler as shown in Fig. 24. The latter practice, however, is more universally used than the former practice, and this notwithstanding the fact that a place or recess is created for the collection of mud and foreign substances.

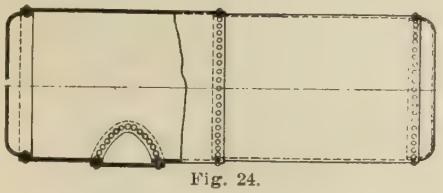

Fig. 24.

A patch applied to the bottom af a tubular boiler, whether applied inside or outside of the boiler, should never be applied with patch bolts. Patches can be readily and safely applied with patch bolts to the fire-box or furnaces of locomotive boilers—and for the reason that there is but little strain on the plate from the centre of the rivet hole to its edge. This is not true, however, with a patch as applied to a tubular boiler, per Figs. 23 and 24. They should be riveted.

The patch as applied in the manner as shown in Fig. 24, can be brought "home"—that is, brought metal to metal against a shell plate, more tightly than if applied in the manner as shown in Fig. 23, Further, the installation of the patch, Fig. 24, can be more readily and cheaply installed than the patch, Fig. 23, and practice has shown that it is

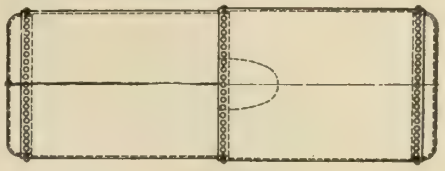

Fig. 25.

better to calk patches to the shell plate instead of the shell plate to the patch. If the boiler is clean, as it should be, no difficulty should be experienced by mud and foreign substances collecting in the recess patch applied as shown in Fig. 24.

Reference has already been made to the cutting of hole for patch on the shell plate. Frequently the shell plate will crack adjoining the girth seam. In such cases the hole should be cut as shown in Fig. 25, and not as shown in Fig. 26—and for the same reason as given in regards to Figs. 21 and 22.

It is not practical to apply the patch to the inside or outside of the boiler and not cut out the defective part when said defective part is in contact with the flames or hot gases. A crack might develop in—say the dome—and in this case a patch could be applied over the crack or defective part without removing same. However, that portion of the shell plate of a tubular boiler in contact with the flame and hot gases, should not and cannot be repaired by applying a patch without removing the defective part of the shell plate. If the patch is applied without removing the defective part, the double thickness of the plate at that point will result in the plate becoming overheated and the patch's length of service will be of a very short duration—

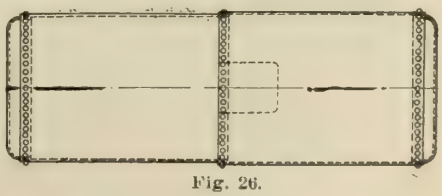

Fig. 26.

less than a day. It is very essential that the underlying principles of the foregoing should be understood, and when understood the repairing of boilers will be a simple matter.

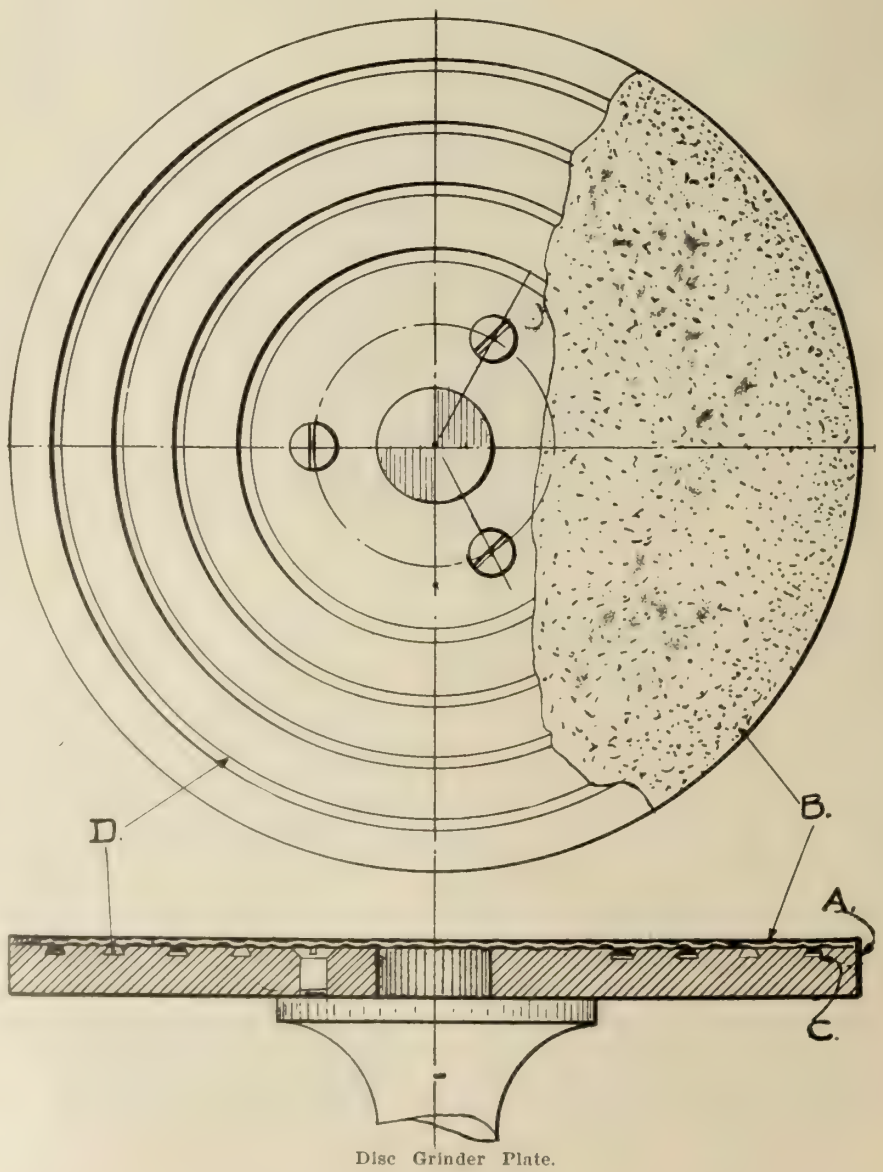
DISC GRINDING.

By J. A. Bradley

The wide application and economy of disc grinding is not as thoroughly appreciated by manufacturers of interchangeable or duplicate parts in this country as in others, and for the comparatively slow development of this method of reducing the surfaces of metals, the makers of disc grinding machines are themselves largely to blame.



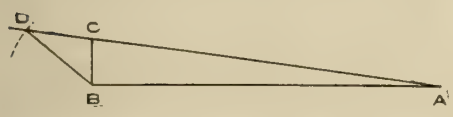
The broad claims made by these firms in regard to economy of operation in the use of unskilled labor has greatly retarded its progress, also the early machines sent out were poorly designed, not having sufficient weight for the high speeds at which they operate, and they soon shook themselves to pieces. The use of unskilled labor for what appeared to be a simple operation soon increased the size of the scrap heap and disproved one of their strong talking points. It also showed that disc grinding requires much skill.

It is true that the use of unskilled labor may be developed in a comparatively short time, starting at the more simple operations and advancing step by step, but if many machines are to be operated the constant supervision of a skilled operator is necessary. The failure of unskilled labor to operate these machines as claimed by the makers, the high cost of maintenance because of poor design, and the difficulty of attaching grinding circles to the plates so that they would remain until worn out, soon developed a prejudice that has not been easily overcome.

Of these conditions all but the latter have become better understood and improved, and while special adhesives for this purpose are available the trouble remains. Another object to overcome that remains, and which met with very little success, was to cut upon the face of the plate a half-round spiral groove. The settlement of this condition against the successful operation of disc grinding will be better understood when one reflects upon the cost of these circles when purchased ready made up in the plate, and that after one has run after a few hours use in machines as far as disc grinding is concerned is totally destroyed as it is next to impossible to replace it.

The accompanying drawing shows a disc grinder plate that has been in use for several years, and while the idea is not new (a patent having expired in March 1910) very few interested in disc grinding seem to have heard of it. It entirely overcomes the difficulty, keeping the grinding circle perfectly flat against the plate until completely worn out. In fact, in making a test as to the relative merits of a plate made as shown and one having a half round spiral groove cut on the surface, it was necessary to use hammer and chisel in order to remove the circle held on with ordinary glue, while the spiral groove plate was coated with a special glue and the grinding circle could be removed quite easily by hand.

In the illustration, "A" is the grinding plate, "B" the grinding circle or surface, a portion of which is shown in the plan view, and "C" the glue or other adhesive substance. It will be observed that there are a number of radial dovetail or undercut grooves "D" cut in the surface, the number depending upon the diameter of the disc. These may be cut upon both sides and grinding discs placed thereon, so that when one wears out the other side may be turned out. In using a plate cut in this way grinding discs may be fastened with an ordinary stiff paste of flour and water, and the grinding disc will last until completely worn out, and when it is desired to replace it, it is only necessary to immerse in boiling water in the usual way, when all the glue or paste will come out.



Disc Grinder Plate.

AUTOMATICALLY PRODUCING CONICAL SURFACES ON A BORING MILL.

By J. H. Williams.

Some time ago, in the shops with which the writer was connected, the problem presented itself of facing some concave and convex conical surfaces by means of a boring mill. The angle which the slope of the cone made with the vertical was greater than 45 deg.,

Layout Diagram—Automatic Conical Surface Producer on Boring Mill.

therefore the method now described was adopted. It may prove of interest to readers of Canadian Machinery, especially as a way has been devised for accurately determining the amount the tool-bar has to be swung over from the vertical position to produce various angles, without employing any "cut and try" methods. The half-tone illustrates one of the jobs in question, and it will be noticed that the head is set over very little, although the angle made by the slope is 63 deg. with the vertical. This is accomplished by using a combination of both the vertical and horizontal feeds, and further by using only the vertical feed on the head doing the work, and the horizontal feed on the other head. Such a method was necessary for two reasons; one being the construction of the machine, which allows only equal feeds in each direction when both feeds are obtained from the one head, and the other that this arrangement enables the proportion between the two feeds to be varied. Thus, we may get for instance, 1-16 inch feed in the downward direction and 1-8 inch or more in the horizontal, or any other combination which is permitted by the feed gears on the machine.

The two heads are connected by a bar, as shown in the half-tone cut, which has the effect of practically making the two into one. On some machines the nut which engages with the horizontal feed screw is made in halves and can be opened and closed at will. On others again the nut is solid, and where this is the case, it is necessary to remove the horizontal feed screw from the head carrying the tool, so that it may be free to move across horizontally under the pull of the other head, exerted through the coupling bar. The next thing is to determine the angle through which the head which carries the tool must be swung in order to produce the required slope. As far as the writer is aware, the following graphical solution of this problem has not previously appeared in print.

Construction of Diagram.

Referring to the figure, we lay off a straight line AB, equal to the radius of the base of the cone to be turned. At B erect a perpendicular BC, equal to the vertical height of the cone. From B lay off a line BD cutting the line AC produced at D. The length BD must bear the same relation to the length AB that the downward feed of the tool bears to the horizontal feed. The angle CBD is the angle which the tool-bar must make with the vertical in order that the tool may follow the slope DCA. Example: suppose we have to turn a cone the radius of whose base is 15 inches and whose vertical height is 2 inches, we first settle upon some ratio for the two feeds. Let us assume 1-32 inch downward and $\frac{1}{8}$-inch horizontal feeds per revolution of the work, which is a ratio of 1 to 4.

Laying out our diagram we make AB equal to the radius of the base of the cone, or 15 inches, BC equal to the height, or 2 inches. As already mentioned BD is to AB as the downward feed is to the horizontal traverse; that is to say, BD must equal 15, divided by 4, or $3\frac{3}{4}$ inches. From B strike a radius equal to $3\frac{3}{4}$ inches, and call the point where it cuts AC produced, D. Join BD and by trigonometry or by measurement find the size of the angle CBD and set the tool-bar this amount off the vertical.

If the ratio of the two feeds is the same as the ratio of the height of the cone to the radius of its base, the tool-bar is not swung over at all, but stands vertical.

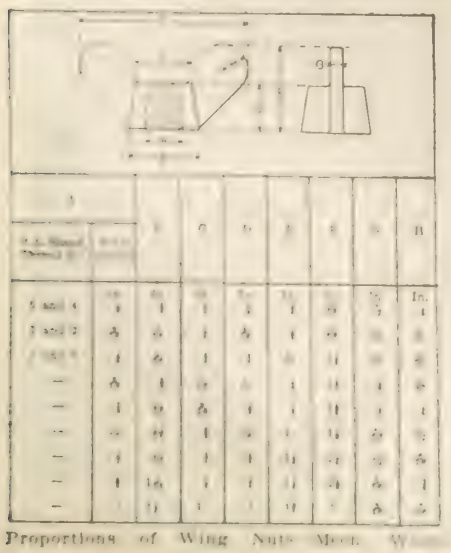
The half tone illustration shows the method being applied to the turning of a conical piston head, often a more convenient way than chucking such a job in a face-lathe; and having the advantage of producing the slope automatically.

Automatic Turning of Conical Piston Head on Boring Mill.

INCREASING PLANER CAPACITY.

By Donald A Hampson

Our shop had a most adequate equipment for planer work and compared more than favorably with any other for twenty or more miles around. Despite the fact that the squeech of the planer belt was rarely stilled, we were so burdened with orders that a goodly pile of castings always lay around waiting their turn to be machined. As foreman, I was chairman of the ways and means committee, and therefore supposed never to be at a loss for an expedient.



One of the planers had two heads on the cross rail and a 15-foot bed, so to it I looked for double service. How I got it, may be gathered from the illustration which shows a job set up on each side of the bed, one a straight

Increasing Planer Capacity.

racing job, the other a 55 degree angular cut on grey iron castings, 7 feet long. With a shorter planer, only one casting could have gone on at a time, and of course, no extraordinary progress would have resulted.

The feed naturally was not what one might term ideal with both heads in operation, still it was pretty close to it, and the net result was a rapid clearing up of the castings pile on the floor. This

Proportions of Wing Nuts Used.

method requires work of a somewhat related form, and within certain limits as to size.

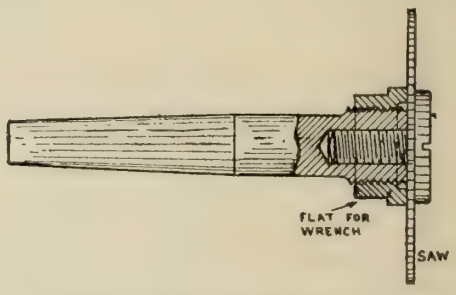
To still further "cut time between acts," as Bullard says, I had two men set up the work and remove it when finished, thus making the most of the work producing hours available.

MAKING PERFECT BLUE PRINTS.

Many novel and patented devices have from time to time been designed for the purpose of ensuring clear blue prints when printing in large frames. One of the simplest of these has been in use in a Belgian factory for many years, and has proved satisfactory in every way. In this factory the prints, which are in many cases of huge steam engines, have to be made of exceptionally large size, and the difficulty of ensuring perfect pressure of the paper in the frames is overcome by using thin rubber cushions the size of the frames, which are placed between the paper and the wooden back. Air is then blown into these cushions by means of the mouth, which gives just sufficient pressure to ensure perfect contact, without bulging the wooden back or the large glass front of the frame. By using this simple device the largest prints can be produced with perfectly sharp lines all through, and spoiled and blurred prints are entirely avoided.—The Dodge Idea.

A SIMPLE ARBOR FOR THIN SAWS.

By Chas. Hattenberger.

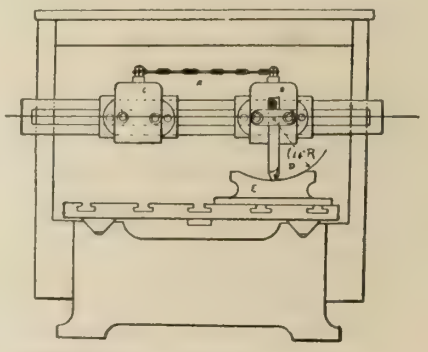


The accompanying cut shows a simple and efficient type of arbor for thin circular saws used for metal slitting.

The taper shank is made to fit the milling machine spindle and the two screw threads are of opposite hand. Thus if the saw is to revolve in a right-hand direction, like the hands of a clock, the outer thread and nut are made right-handed, while the centre screw is made left-handed. The strain on the saw has a tendency to make the nut and screw close in towards each other, and the greater this strain, the tighter the grip.

HOW TO CUT CURVE ON PLANER.

By H. D. Chapman.



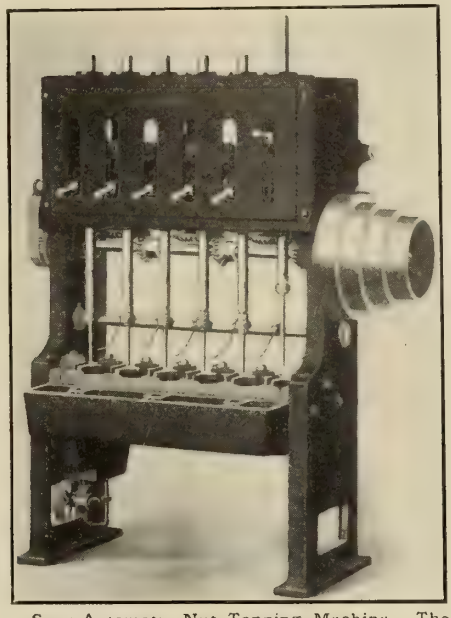
A number of castings were recently brought to the shop where the writer works. Each casting was to be finished 24 inches square, and had to have a 14-inch radius cut through the center as shown at E in the accompanying drawing. The job was too large to clamp on the lathe carriage and allow for a cut of 14-inch radius, so after a little thought we rigged up the planer as shown in the accompanying drawing. Five of the castings were clamped on the machine at a time, and the job was soon finished. The tool was set central with the casting. The planer head B was locked to the cross beam, but the swivel was left free to turn. The head B was connected to the head C by the chain A. The cross feed was put on the

Simple Arbor for Thin Saws.

head C, and it swung the head B and the tool through the desired sweep. A first-class job was done in a very short order.—Scientific American.

It's a good plan to assume that the builder of a machine knows a little about it and that it will pay to follow his instructions, at least till you have found a better way. If any directions seem complicated, it is a safe bet that there is a reason for it. No sane builder wants to make it any harder than necessary to learn how to operate his machine.

How to Cut a Curve on a Planer.



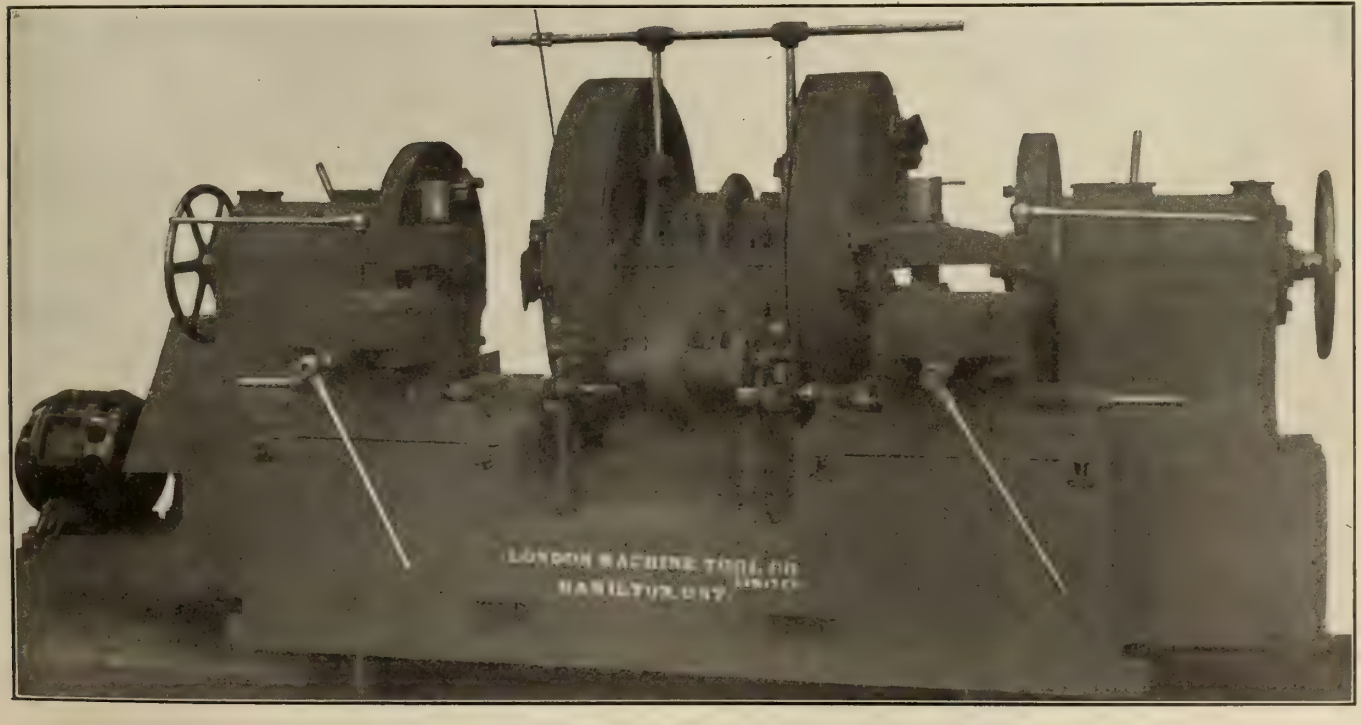
DEVELOPMENTS IN MACHINERY

A Record of New and Improved Machinery Tending Towards Higher Quality and Economical Production in the Machine Shop, and Blacksmith Shop or Planing Mill.

SEMI-AUTOMATIC NUT-TAPPING MACHINE.

The National Machinery Company, Tiffin, Ohio, manufacturers of bolt, nut and forging machinery, have perfected a new design of Semi-Automatic Nut Tapping Machine, which is shown in the accompanying illustration. In this new tapper, rough hot pressed nuts are tapped as readily as cold punched nuts, and the objections against the purely automatic tapper, due to "sticking," etc., when small burrs are encountered on rough hot pressed nuts, is overcome. The tap spindles in this design are raised and lowered automatically, and the machine "sets the pace" for feeding. The operator does not experience fatigue, as on the foot-lever tapper, due to treadling, is able to easily keep pace with the machine during the day, and secure the maximum output. Outputs on this machine range from 60 to 80 per cent. greater than are possible on the foot lever tapper.

The revolutions of the tap spindles raising and lowering, can be varied to correspond to the number of threads on the tap being used. This eliminates "non-productive" tapping time, tap running idle in the nut after it is tapped, and quickens the "pace" for feeding, set by the machine. The variations in the revolutions of the tap spindles are secured through a single lever quick-change speed box on the cam shaft. The raising and lowering of the tap spindles is accomplished by six three-step cams carried on a horizontal shaft in the rear of the spindle housing. These cams engage with hardened steel rolls carried in the spindle levers. The cam shaft shifts laterally, so that the various cam faces or steps can be engaged; in this way the "staying" or resting time of the tap when raised, can be altered to meet the needs of the operator for feeding the machine and emptying the taps. The life of the tap also, is longer than generally experienced in the foot-lever tapper, as the cam movement causes the tap to lower gradually, instead of dropping into the hole with the weight of the spindle back of it, causing it to bind, and resulting in broken taps, stripping of threads, etc., so common in the operation of the foot-lever machine.



Semi-Automatic Nut Tapping Machine. The National Machinery Co., Tiffin, O.

An automatic socket allows the tap to be removed or inserted while the machine is running, and ejects the tap automatically when the shank becomes filled with tapped nuts. This new design is built in 1 inch capacity with six spindles, and 1½ inch capacity with ten spindles. National Circular 1010, gives a full description of the machine, which together with a National wedge Grip bolt header and new friction-slip fly wheel, a National quadruple bolt cutter and National die sharpener, all of direct motor drive designs, can be seen in operation at the Master Mechanics' and Master Car Builders' conventions, Atlantic City, June 14 to 16, and 19 to 21 respectively.

COACH WHEEL LATHE, THE G. T. R. SHOPS, MONTREAL.

There was recently put under test at the G.T.R. shops, Montreal, a 42-inch coach wheel lathe, illustration and leading features of which, together with

42-inch Coach Wheel Lathe at G.T.R. Shops, Montreal.

data of the test are herewith described. The test was run under the supervision of J. Coleman, car shop superintendent, G.T.R. System, and W. Pitt, foreman of car shops, G.T.R., Montreal. The results constitute what is believed to be a world's record, and have an added value and importance from the fact that this machine was the first of its particular type. It is believed that later productions will show still more satisfactory results, and while only of recent introduction on the market, installations have been made by the Grand Trunk Pacific, Temiskaming and Northern Ontario Railway, and the National Transcontinental Railway.

Description of the Lathe.

The machine is of an extra heavy type, designed for turning out railway coach wheels at a rate heretofore unobtainable. The driving mechanism consists of 2 face plates, 56 inches in diameter, having opening cut in same on one side, to admit of axle; each driven by an internal gear of steel of coarse pitch. The spindle is 16 inches in diameter, and has 2 bearings 14 inches long, accurately scraped. It is open on one side to admit the largest axle required, and the construction of the machine relieves it of all torsion. The bearings are bronze bushed. The pinions meshing into the internal gear are steel, the teeth being cut from the solid. The bearings supporting these gears are phosphor bronze, and are 5⅞ inches in diameter by 11 inches long.

The centre head supporting the 2 internal gears has a wide bearing on the base, and is secured to it by heavy bolts and dowels, making an exceptionally rigid construction. The method of taking the insert is very simple, there being two screws to loosen up, and the section to drive out. The shape of the gear ring also tends to rigid construction by which there is no vibration. To the face plates are secured drivers of the latest approved form, giving ample driving capacity to the machine. The [illegible] spindles of large diameter, [illegible] powerful self-[illegible] for gripping the [illegible] are adjustable in and out on a distance of 12 inches, and are moved by motors or screws operated by buttons on each end. These motors need not be over 2 h.p. capacity each. The [illegible] and rests are extremely massive, and provided with means for quickly releasing tool and securing it in position. The feeds are four in number, and vary from [illegible] to [illegible] of an inch per revolution. Ample room is made for the work required. The base is stiff and deep, with ample [illegible] for bolting the work to foundation.

Advantages of this machine are that the power is not transmitted through an open side shaft. The strain is transmitted entirely through the gear; the bearing having only a steadying action and no transmitting function. There is no worm gearing to absorb energy, and the heads being moved backwards and forwards by power, the attendant is relieved of much incidental trouble. The tool post is of a powerful type, and is operated by a large screw of coarse pitch, having differential threads. The weight of the machine is about 55,000 pounds, and its recommended driving equipment is a 40 h.p. variable speed motor, with speed variation 3 to 1, or a constant speed motor giving 2 speeds, 10 and 16 feet, by means of friction clutches.

Test Data, 42-inch Coach Wheel Lathe.

Test Particulars.

The machine was operated during the test by two mechanics and two helpers, while another man took electrical readings. The wheels were Krupp B.V.G. Pairs 1 to 31 were 38 inches, 5x9 wheels, pairs 32 to 40 were 38 inches, 4½x8 wheels. The forty pairs of steel tired wheels were turned out in 9 hours and 35 minutes, and the tools used, only required one grind for the entire operation.

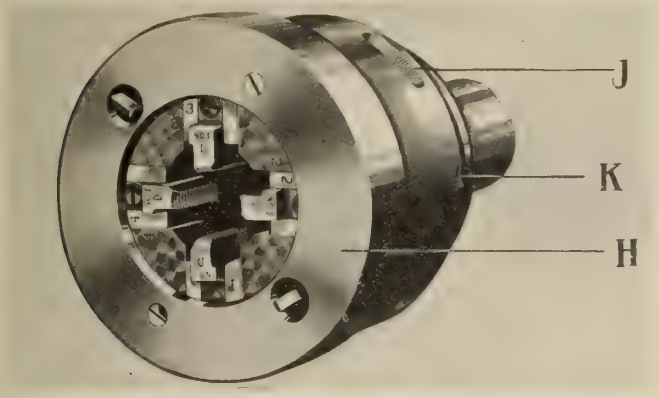
The lathe is manufactured by the London Machine Tool Co., Hamilton, Ont., and has been developed in its leading features, which are patented, by the general manager of the company, E.G. Yeates.

A NEW OPENING DIE.

A departure from previous designs allows this die to be operated while being revolved. It is designed particularly for use on screw machines where the threading spindle is revolved. In addition, there are several other important features which have been carefully covered. The chasers can be removed from the jaws without displacing any of the other parts, and are so designed that they will cut a practically perfect thread without the use of the follow-up cam; a very essential point when used on the rotating spindle. A liberal adjustment for size is provided in the cam arrangement on the chaser blocks, and this is controlled by a fine pitch screw with micrometer graduations plainly marked.

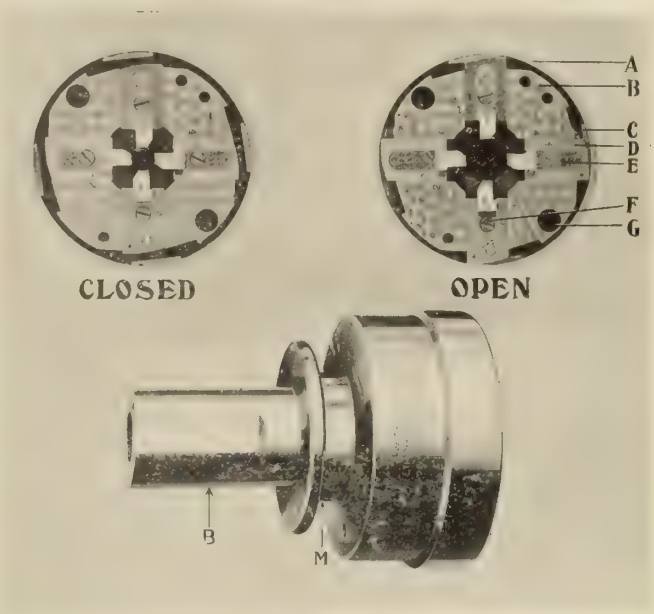
The jaws holding the chasers, and the cam surfaces controlling the closing of the die are hardened and ground with a wide bearing on the cam surface, which holds the jaws firmly in position when the die is closed. No springs are connected with the parts on which the adjustment of the dies or the operation of the closing cams depend. As shown, this new design of die requires a small number of parts and these are so arranged as to make it easily taken apart and reassembled, although this is seldom necessary, as the head cap prevents chips entering the working parts, and the internal arrangement of the head leaves plenty of room between, except in the matter of the cam faces and the surfaces they bear on. Grit carried by the oil and other foreign substances works into these clear spaces and out of the head through holes provided for the purpose in its sides. The die may be thoroughly cleansed by simply removing the cap "H" from the front face and washing in oil or compound. No other parts need be removed. All details of the die are made interchangeable, to facilitate reassembling or replacement of worn or broken parts.

This die has been developed by The National Acme Manufacturing Company, of Cleveland, for use on their Acme automatic multiple spindle screw machines and other machines with revolving threading devices, after over two years experimenting with the standard makes of die heads and departures from same.



Die Detail.

A—Body holding the working parts.
B—Head holding the chaser blocks.
C—Cam operating block.
D—Chaser block, with cam for adjusting milled on rear end.
E—Chaser which can be removed by removing screw "F" only.
F—Screw holding chaser.
G—Screws holding B to A.
H—Cap protecting working parts from chips, etc.



K—Adjusting screw.

J—Micrometer graduations for adjustment.

M—Groove for closing shoe.

SIBLEY FOUR SPINDLE HI-SPEED DRILLING MACHINE.

In this four-spindle Hi-Speed drilling machine made by the Sibley Machine Tool Co., South Bend, Ind., there is endeavor to combine all the features which add convenience and effectiveness without undue complication. The individual square tables are close together and can either be used as one table for the whole machine or any one of them may be raised or lowered to accommodate different size jigs. Each spindle is independent of the others in operation, and each has its separate quarter turn countershaft, instead of single clutches for each machine. This method of drive has been selected with the idea of delivering the full amount of power to each machine, and to eliminate the troubles incident to the use of friction clutches. A gear pump driven from one of the countershafts supplies lubricant from a large tank to all four spindles, and to this tank all the lubricant returns through drains on each table. The usual geared tapping attachment is fitted to the fourth spindle.

Distinctive features of these machines are their direct drive, and gear case location on top of the column. The operator can take care of all four spindles, without being obliged to go around back or side of the machine for speed changes or adjustments. The machine may be started and stopped, speeds and feeds changed and spindle returned, from directly in front. The same type is manufactured with two or three spindle arrangements.

Sibley Four Spindle Hi-Speed Drilling Machine.

THE BOND HANGER AND COUPLING CO., ALEXANDRIA, ONT.

Mr. Charles Bond, Philadelphia, Pa., president of the Bond Hanger and Coupling Co., Alexandria, Ont., visited the plant a few days ago, and presided at a meeting of shareholders. Mr. Bond represented the American interests, while those of the Canadian end were looked after by H. Munro and J. McIntosh. M. H. Graham was appointed secretary-treasurer and general manager. The report of business done since the inception of the company and commencement of operations was considered highly satisfactory, and in view of the likelihood of a substantial and steady business increase in the near future, steps were taken to add to the machine equipment so as to cope with it.

Before kicking about failure of societies and associations to live up to your expectations, just hold a little inward communion with yourself, somewhat along this line: "What have I contributed toward exchanging expectations for results?"

Vol. VII. June, 1911 No. 6

CANADIAN MACHINERY.

With this issue of Canadian Machinery, Mr. Peter Bain assumes responsible editorship. Needless to say Mr. Bain's long practical experience in the various departments of machine shop work, his success as a designer and his thorough technical training, eminently qualify him for the position.

Mr. J. H. Williams, asst. shop engineer, the C.P.R. Angus shops, Montreal, becomes associate editor, and he too brings to the work of our paper, a wide and comprehensive knowledge of the most modern machinery practice. On another page will be found a brief account of Mr. Williams' training and experience.

We bespeak our readers' co-operation by correspondence, inquiry and contributed articles in our editorial work.

A QUESTION OF ENDURANCE.

Machines are designed to perform certain operations involving great accuracy with rapid output, and much ingenuity is displayed in the arrangement of the various mechanisms which lead to successful attainment. Does the active material, if we might so term it, receive that care in selection of kind and quality, to put it on a par with the other effective features, or may it be left unwittingly the weak link in the chain? It does seem that the latter is in many cases an existent condition, and as a consequence, much skill in design or accuracy of workmanship, becomes wasted immediately the machine or its detail gets into service.

Gear wheels strike us as being pertinent examples of elaborate precaution taken to secure correct form teeth without due regard to teeth material in the light of operating conditions. Wheel teeth although perfect in form will remain so through a brief period of operation, and the beneficial effects looked for, will have disappeared long before the life of the wheel is over, unless steps are taken to secure material which will not only stand up to the work by its quality, but will make appear reasonable and right the time and skill expended on teeth form.

Many examples might be quoted to show the inconsistency of spending much labor and skill on material unworthy of and unsuitable for its selected service, and our drawing attention to the subject, may as these examples suggest themselves, lead to a material being selected nore in conformity with the care and cost of design and workmanship.

A WORD TO THE APPRENTICE.

The apprentice of to-day if he wishes to be spared not a few vain regrets in after years, should take time to realize the advantages he enjoys over his predecessors of fifteen or twenty years ago. Then, even in large shops very few facilities were offered or were available to a lad for learning the technical side of his trade, with the consequence that his prospects for becoming anything beyond a skilled mechanic were more or less remote.

The care and attention bestowed on the apprentice today is such as to make some of us old timers a trifle jealous, and to wish that we had been favored with an equal opportunity. In spite, however, of all that is being done for them to-day, we fear a goodly number of apprentices are more or less unappreciative and do not take advantage of all the opportunities offered that they might. We know that quite a large number only keep themselves sufficiently efficient to scrape through the periodical examination which qualifies for increased wages.

Reference has been made to the fact that the older generations of us look jealously on the opportunities of the present. It is problematical, however, whether we would have availed ourselves much more so of these additional channels of knowledge than do the youth of today. Competition is keener, and a higher standard of competence is required, therefore while opportunities for the acquirement of a more thorough practical and technical training are increased, they are not in any sense superfluous. The percentage acquired of the total knowledge available, has been and still is low comparatively speaking, and while we would place no restriction on the recreations of the present day apprentice, we suggest his diligent application to and study of the problems of his profession, so that at a period of 5 or 10 years earlier in age than that of his predecessor of another generation, he may have the mature experience at least, of the latter.

TRADE CONVENTIONS AN AID TO PROGRESS.

Within the last few days, two important conventions have been held; those of the National Machine Tool Builders' Association at Atlantic City, and the American Foundrymen's Association and allied bodies at Pittsburg. The meetings of each are declared by competent judges to have been the most successful in every sense of the application of the word, of any previously held.

One feature that struck us, was the high quality and wide range of subjects discussed by the authors of papers, and the evidence of keen interest in them by the delegates present. At the Foundrymen's Convention an added attraction was the manufacturers' Exhibit, and we feel safe in saying, that never before in the history of the foundry, has such a visible, varied, valuable and magnificent operating display of foundry equipment been

brought to the notice of so large a representation of foundry and general engineering delegates.

The exhibit showed the wonderfully rapid progress that is being made in foundry engineering development, and goes a long way to eliminate the idea most of us have, that this department is not keeping pace with the others to which it is allied. This annual convention, or meeting place out in the open as it were, has done and is doing much to break down prejudice of the molder against the use of automatic machinery, and to convince the manufacturer that observation by others of his product does more to raise its standard than would the careful conservation by him of its supposedly valuable trade secret.

We are glad to be able to speak commendingly of convention work, effecting as it does much relief to those who bear the burden of bodily labor and increasing their earning capacity together with those who employ them.

It is one of the most efficient factors in cementing a pleasant relationship between employer and employe, meeting as they do on common ground and realizing in a way utterly impossible under ordinary work-a-day conditions, that each is necessary to the other and has a live personal regard for their mutual welfare.

EFFIENCY AND CONTENTMENT OF EMPLOYE.

In the business management section of the present issue is to be found an article "Profitable Ethics," from the pen of David Van Alstyne, vice-president, the Allis-Chalmers Co., Milwaukee. With the sentiments expressed, we are in general sympathy, yet we are disappointed to find no reference made to, or panacea prescribed for that large percentage of labor whose employment is more or less intermittent, and who are treated by large public corporations particularly, much in the same manner and with probably less concern as to consequences, than any of us treat the doffing or donning of some article of attire.

It is no uncommon experience to read in the daily press that some large corporation has discharged 500, 1,000 or 2,000 employes, part of a payroll of it may be, four or five times these numbers. With a majority, such is a frequently recurring incident of their existence, and being so, must necessarily militate against all organized efforts at high efficiency, no matter how skilfully applied and directed. Organized systems to secure results in efficiency will not and cannot bear effectively on these men. Pay them as high wages as you may, work them as hard as you can, and you will look for their contentment with a microscope, yet not find it. They do not realize that the main springs of the great corporation know them each personally through their work, and cannot do so because such knowledge does not actually exist in their case individually. Of the employes who constitute the payroll, irrespective of trade, weather or stock trading requirements, they form no part, and being sensible to their position, act and work accordingly. So long as men are taken on in great batches immediately some large contract is secured, and discharged again as soon as it is completed, just so long will inefficiency of performance have to be borne, and natural and righteous discontent be a serious factor of reckoning.

A man at his best must have an ambition, and in addition the opportunity for its exercise. The ambition is his inherently and instinctively, yet it may be and is stifled and killed outright by want of opportunity. The opportunity is the gift of the employer and will in its generous distribution be not wanting in generous returns. Corporations or individuals who in their desire to gobble up everything at sight, although the undertakings be far in excess of the numerical strength and equipment capacity of their organization the year round, supply the conditions of which we have spoken, and until some effective remedy which will either modify or obliterate altogether the possibility of any individual or body corporate doing so, moral responsibility of the employe, his efficiency, his self-respect and contentment, will maintain a standard far below that which our twentieth century progress and civilization calls for.

THE ATTRIBUTE OF LOYALTY.

It is generally admitted that the first and main consideration with the great majority of us, is to earn the most comfortable competence attainable from our labor. In doing this we may be more or less disloyal to ourselves and to those whom we serve. Naturally, the man who is disloyal to himself, cannot fail in exercising the like spirit to his superiors, yea even his equals and inferiors. We sometimes remark that a certain individual is foolish to his own best interests, yet we don't mean to imply the slightest suspicion of disloyalty. As a matter of fact his fault may be, that he is "a good fellow," and as such, no streak of the disloyal nature would be likely to exist. There is nothing deliberate in his foolishness, although its effects may be hurtful to himself and his employer. The disloyal man on the other hand, acts with studied deliberation, and looks for effects correspondingly. He is in the abstract, selfish, nursing a grouch born of a limited outlook, and is a decided acquisition in his absence, to any social function or to an employer's pay roll.

Loyalty is not a onesided affair, however, although in the relationship of master and servant, employer and employe, the disposition is rather inclined to consider it in this wise. We hear much of the loyalty or disloyalty of the employe, and little of either on the part of the employer. As subjects of the British Empire we need be no more loyal to it and its King, than he be to us and it. Correspondingly, there should be reciprocated loyalty between master and servant, and only in its full and free display by each, will the best results in efficiency be obtained and the highest remuneration be secured by both parties. Loyaly on the part of the employe need have nothing cringing in its get-up, should be outspoken in its demands when opportunity requires, and forbearing and appreciative under adverse circumstances. Loyalty on the part of the employer should consist in a lively personal interest in the employe's work and welfare, individually or collectively as conditions permit, and the careful consideration of requests and suggestions from that source.

There is a certain diffidence apparent in all lines of business, on the question of proffering a request to an employer for additional tangible recognition of service and which is due to neither more nor less than uncertainty as to how it will be taken. A suspicion exists that the employer will not be so loyal after refusing the request, and will take the first opportunity of rewarding what we opine was insolence shown and get rid of us altogether.

Such a conclusion is unfortunately a very natural one, and we concentrate our efforts to forestall his intent and get even with him. Our loyalty has vanished, with or without justification, and the training of years has been sacrificed. An old saying, "that there are good and bad of every sort" seems to us peculiarly applicable to this feature of loyalty to which we have referred, and our experience has been, over a goodly number of years and a fair sprinkling of individual employers, that even after a request refused they are still to be trusted.

POWER EQUIPMENT & APPLICATION

Expert Descriptive Articles Dealing with Selection and Purchase of Most Suitable Power Equipment for All Purposes, its Proper Application, Installation, Operation and Treatment.

DOUBLE HELICAL GEARING.

Double helical gears have been [illegible] for some years with cast teeth and extensively adopted for certain classes of heavy work where, although it is [illegible] consideration, but owing to the practical difficulties of making them with machine cut teeth they had been superseded for high-speed work by [illegible] gears with straight teeth. During the last few years, however, the cutting of double helical teeth has been considerably developed, and they are now produced with the same facility as straight-toothed gears.

When correctly designed and accurately cut double helical gearing possesses advantages both in principle and utility [illegible] from any other type. The advantages may be briefly summarized as follows: 1. Continuity of engagement, which eliminates vibration and enables a greater load to be transmitted. 2. Pinions with a small number of teeth (say 4 or 5) can be used, and in this way high ratios can be obtained without using a wheel of abnormal diameter. 3. A higher efficiency than in the case of straight-toothed gearing is obtained, particularly when the number of teeth in the pinion is small, due to the direct action of the teeth during engagement. In straight gears the line of contact are parallel to the axis of rotation, consequently the phases of engagement are constantly changing, and the action is uneven. With double helical gearing the line of contact is a curve extending diagonally across the tooth, and all phases of engagement occur continuously. A silent running at high speed is obtained, owing to the gradual engagement and absence of vibration. There is no necessity for using soft pinion pinions, such as rawhide or [illegible]

Suitable Materials

As regards suitable materials it is generally found that a [illegible] pinion working with a [illegible] gives the best results. In [illegible] where [illegible] must be reduced, pinions made from [illegible] nickel steel, working with cast iron wheels, can be advantageously used. There are two systems of cutting double helical wheels from solid blanks. One requires the use of end mills made to correspond to the space to be cut, and the other is a generating process. In both cases similar to those used for cutting straight wheels are used. In the former case the end mill cuts both the right and left hand portions of the teeth. The mechanism in the machine for giving the lead to the blank has therefore to be reversed when the tool reaches the centre.

The use of end mills for this work entails some disadvantages, as these tools cut slowly and wear out quickly. Besides this, when reversing at the centre a radius is left by the tool at the place where the blank leaves the cutter when changing its direction of rotation. This radius should theoretically be a sharp corner, and unless some compromise is effected, it fouls the point or apex of the tooth which is intended to gear with it. As a consequence the point of the tooth must be chipped or filed off by hand, otherwise the radius must be recessed by a special tool in a separate operation, after the cutting of the teeth has been completed.

Generating System

The generating system by means of hobs is a continuous process. Two hobs are used, one right-hand and one left-hand thread; these respectively cut the right and left hand portions of the teeth. The shape of the hob threads is made to correspond to a rack tooth, and they are both geared with the blank so as to give the correct ratio for the number of teeth to be cut. The machine has also a special mechanism to give the requisite lead to the blank for the desired helix.

Gears made by this system have the teeth staggered—i.e., the tooth on one side is opposite the space on the other. This has a similar effect to halving the pitch, and is in this way conducive to smooth working with a small spiral angle. A further advantage in this system is the continuous rotation of both the cutting tool and the blank, which prevents backlash in the machine having a deleterious effect. No intermittent dividing mechanism is used, and therefore there is no risk of inaccuracies in spacing, which are sometimes experienced with other processes.

The spiral angle should be as small as is consistent with the attainment of continuous engagement. In determining this angle the proportion of the face width to the pitch must be taken into consideration. It is therefore usual to adopt a certain spiral angle as a standard and to make the face width a fixed projection of the pitch. The angles usually adopted are 45 degrees and 23 degrees, with a face width of three and six times the pitch respectively. A large angle is generally considered to be a disadvantage, because when running under heavy pressure wedge action occurs between the teeth in contact, causing friction and decreased efficiency. It is therefore advisable to use a small angle and a comparatively wide face width.

The following particulars and formulae are applicable to double helical gears cut by the generating process, with a spiral angle of 23 degrees and a face width six times the pitch, for ratios up to 6 to 1, afterwards increasing with ratio.

Let p=pitch in inches; P=tooth pressure in pounds at the pitch line; W=width of face in inches; V=pitch line velocity in feet per minute; r=ratio of reduction; K=permissible stress.

Then

$$P=\frac{\text{B.H.P.}\times 33{,}000}{V}=\frac{pWK}{2}$$

For ratios up to 6 to 1, $p=\sqrt{\frac{P}{3\times K}}$

For ratios between 6 and 10 to 1, W=rp (r=ratio to one).

$$p=\sqrt{\frac{2.5P}{rk}}$$

Proportions of teeth:—

$$\text{Thickness of tooth}=\frac{P}{2}$$

$$\text{Addendum}=\frac{0.89\times P}{3.14}$$

$$\text{Dedendum}=\frac{1.05\times P}{3.14}$$

For ratios above 10 to 1 special treatment is advisable, and no fixed rules can be laid down. Each drive should be considered with regard to the general conditions.—Mechanical World.

PRODUCING IRON BY ELECTRICITY

On Nov. 15, 1910, the Swedish Government commenced operations in the experimental production of pig iron by electricity on a scale sufficiently large to be considered of commercial magnitude and to approximate closely the conditions of actual commercial manufacture. Without good coal, and facing a rapid diminution in the supply of wood available for charcoal, the Swedish iron industry has felt that its salvation lies in smelting with the cheap electric energy developed from the country's abundant water-power.

A contract was entered into with the directorate of the water-power at Trollhatten to take 3,000 horse-power per annum for three years at $2,680 per year, and this contract was guaranteed by the Crown: The installation is designed to produce about 20 tons of pig iron every 24 hours, or, with continuous operation, 7,300 tons per annum. About 30 men are employed. The utmost secrecy prevails regarding the operations, and no official news of the results is expected for some months. The local press, however, has stated that the operations of the experimental plants have completely fulfilled all expectations and have proved that ore can be electrically reduced with a saving of two-thirds of the coal used in the old-style blast furnaces.

There seems to be a feeling among iron manufacturers that the experiments are proving the practicability of the process, and it is reported that other furnaces are being planned. It is hoped that by the end of 1911 there will be at least four electrical blast furnaces in operation, producing at the rate of 30,000 to 35,000 tons of pig iron per year on a consumption of 12,000 electrical horse-power.

It is reported that tests have been made of the Trollhatten electric pig iron at a mill in Lotrop. Those tests proved that the wire intended for wire rope is of specially even and good quality.

Correspondence

Comments on articles appearing in Canadian Machinery will be cheerfully welcomed, and letters containing useful ideas will be paid for.

Information regarding manufacturers of various lines, with their addresses will be supplied either through these columns or by letter, on request. Address letters to Canadian Machinery, 143-149 University Ave., Toronto.—Editor.

Use of Common Salt.

In answer to questions on page 107 of the April issue of Canadian Machinery I submit the following :—

(1) The proper method for melting common salt for heating tools or cast steel, is to fuse it in a cast iron crucible bricked in a furnace ; the operation being as follows :—Cover the bottom of the crucible about one-third inch deep with soda solidly rammed down, and fill this crucible up to the edge with common salt ; then heat until fusion is complete. Now add gradually to the melt, enough common salt to fill the crucible, and then add about 5 per cent. by volume of saltpetre and 10 to 15 per cent. of potassium chromate.

Yellow prussiate of potash in small pieces is added to the melt as required, a larger quantity of it being used if the cementing effect is to be increased. In using the yellow prussiate of potash it must be borne in mind that the vapors evolved are very poisonous and should be removed by a pipe.

(2) By the addition of a small quantity of readily fusible soda (carbonate of soda) and a small quantity of saltpetre the fluidity of the melted mass is increased.

(3) Common salt will become a fluid at about 778 degs. by the use of carbonate of soda and a small quantity of saltpetre, it will become fluid at a much lower temperature.

(4) I would advise the use of common salt.—I. S. Barkey.

Societies and Personal

W. E. Siler, shop engineer, C. N. R., Winnipeg, has taken a position as superintendent at the Canadian Fairbanks Co. plant, Farnham, Quebec.

* * *

Arnold M. Bennett, chief chemist, the Montreal Steel Works, Ltd., has been appointed works manager with Catton & Co. Yorkshire Steel Foundry, Leeds, England, and sails by steamer "Megantic" on 8th July from Montreal. Mr. Bennett has been with the Montreal Steel Works since Nov. 1905, and previously held the position of chief chemist with Samuel Osborn & Co., Sheffield, England, for seven years.

* * *

A complimentary banquet was tendered Mr. John McClary, London's greatest captain of industry, at the Tecumseh House recently, by the Board of Trade. Over one hundred of the business and professional men of the city were present to honor the guest. An illuminated address was presented to Mr. McClary. Short speeches of congratulation were made by President Reason, Sir George Gibbons and Mayor Beattie.

Dr. Reason presided, and he tendered Mr. McClary the congratulations of the Board of Trade.

* * *

It is announced that the annual convention of the Canadian Electrical Association will take place this year at Niagara Falls, Ont., on the 21st, 22nd and 23rd of June. It was the original intention of the managing committee to hold the convention in Winnipeg, but it is felt that it would be better to postpone the holding of such a gathering in that city until the association becomes better organized in the West. The last convention at Niagara Falls was in 1906. Then some of the great power plants were only in progress of construction. Visitors will now be able to see them under different conditions. Mr. W. L. Adams, of the Ontario Power Company, Niagara Falls, has been appointed chairman of the committee of arrangements, and Mr. W. A. Martin, assistant general manager of the Toronto Electric Light Company, chairman of the papers committee.

* * *

The ninth semi-annual convention of the National Machine Tool Builders' Association, held at Atlantic City, N. J., Thursday and Friday, May 18 and 19, was a notable meeting, the papers and discussions being of exceptional value to those in the machine tool making industry. It was the eighteenth convention the organization has held. An indication of its success is contained in the remarks of Murray Shipley, Lodge & Shipley Machine Tool Company, Cincinnati, who at the end of the third session, in proposing a rising vote of thanks to the speakers, remarked : "This convention is the most successful the association has ever held, inasmuch as the papers presented and their discussion have brought us particularly close to the great problems in our business." There were about 150 members and visitors in attendance at the meeting, and remarkably few of them neglected any of the sessions. A large measure of the success of the meeting was due to the very efficient manner in which President F. A. Geier conducted the programme, with the able assistance of secretary C. E. Hildreth.

Gossip of the Trade.

The Canadian Fairbanks Co. has been awarded the contract for the largest automatic grain-weighing scales yet built, by the Montreal Harbor Commissioners for their new two million bushel elevator, No. 2. Fourteen automatic weighers make up the contract, and installation is required before the opening of navigation in the spring of 1912. The new installation will require the services of one man only in attendance.

* * *

The John Inglis Co., Strachan Ave., Toronto, are negotiating the purchase of a piece of land adjacent to their works, on which to erect a large and up-to-date grey iron foundry. With this additional departmental capacity, their plant will be more able to cope with the increasing demand for heavy machinery manufacture, and rapid and economical production.

SYSTEMATIC BUSINESS MANAGEMENT

Practical Articles for Managers, Superintendents, and Foremen, to Assist in Carrying on the Business Economically and Efficiently.

PROFITABLE ETHICS.

David Van Alstyne **

Business is war and money-making is and always has been the chief motive of all efforts at progress. In the present organization of society it is inevitable that money-getting shall be primarily our inspiration, and indeed it is doubtful if any other motive will ever be practicable, despite the Utopian program of the socialists who are looking forward to the time when the love of achievement will be our inspiration and the getting of money unnecessary. On the other hand, unrestricted money-making like any other dissipation overdone, is not good for the health of the body politic. The chief manifestation of the disease is in the extremes of wealth and poverty; the former of which is unnecessary, and the latter ethically and therefore morally wrong. Because poverty is wrong it will not be permitted to continue always.

Potent Factors of Progress.

Among the factors of progress in our social organization, perhaps the most potent are the employers of labor, the managers of men. The power of the church, of sociologists and philanthropists to bring about needed reform is insignificant in comparison with that of employers. The social reformer, who would effect his reforms through the employer, is confronted with the task of increasing the employes' wages and at the same time increasing the employer's profits. It is the instinctive desire of every employer to promote the welfare of his employes to the fullest possible extent as long as it does not interfere with his profits. His philanthropy and cost will go not extend much beyond this. Maximum output, lowest cost of production and highest wages can be accomplished through accurate knowledge of what every detail of the business actually is, the investigation of what it should be, and the bringing of the actual up to the standard and keeping it there in proportion to the increase in magnitude of the business the importance of the personality of the leader decreases, but the system and organization through which he exercises his personality, increases. It is through a systematic control of employes of the rank and file that the relative waste of time and material, rather than through the personal influence over his immediate subordinates. The measure of the efficiency of an organization is the extent to which the enthusiasm of the individuals in it is maintained through the organization and not through the personalty of the man at the head of it.

Of promoters or captains of industry whose far-sightedness indicates where development is needed and where money can be made, there is no lack; but managers who will patiently standarize each detail in the operation of their business and get the maximum out of it, are exceedingly scarce. Under detail-control management, as little as possible is left to individual judgment, but the movements of every man, every piece of material, and the expenditure of every dollar are guided according to a prearranged schedule. Not the least asset created by the management which has accurate record of the individual, is the impression made upon the employe that the highest officials know of him personally; that he is less subject to the whims and prejudices of his immediate superior and that he is recognized as an essential part of the organization, which arouses an enthusiasm that connot be too highly valued.

Employer and Trade Unionism.

Management through control of details takes advantage of the fact that few men know how to work efficiently and few employers know definitely what they should expect of their employes or their money otherwise expended. Men do not object to hard work if they are well paid and contented, and the harder they work within reasonable limits, the more contented they are. Whenever the employer can create the feeling that the sole object of his official existence is to get the most out of his employes for the money invested in them, and that he realizes this can be done only with the best paid, most thoroughly contented employes, he has won his point and need waste no further effort to destroy Unionism. He will find that he has accomplished all that is necessary or desirable in modifying radical Unionism and that it is as much appreciated by employes as employers.

Assuming that detail-control will produce and maintain maximum output, best quality, lowest cost, higher wages and contented employes, and that as a consequence, it meets with the approval and support of employers, what results may we not be justified in looking for toward an amelioration of some of the social evils which exist to-day, chief of which is the extremes of wealth and poverty? It is true that when all concerns in the same business are equally well managed, no one of them will have an advantage and the same competitive conditions will exist as before; but the next step forward will be from a higher plane.

Is it not safe to conclude that those employers who have had the experience and the profit, will be convinced that the most ethically conducted business is the most profitable, and will it not be a definite and concrete way of getting into practical use those theoretical ideals so attentively listened to on Sundays, but so regularly forgotten on week days? Every man who is willing to work is entitled to a living, and no man is entitled to so much, that somebody else must go hungry.

HANDLING MATERIALS AND MACHINERY.

In spite of the many and strenuous efforts which are made, from time to time, to systematize manufacturing establishments and to reduce the cost of production, it is almost impossible to go in the average shops without being impressed with the opportunities for reducing the cost of handling material to a considerable extent.

Work from the screw machine will be tossed promiscuously into barrels or boxes, so that it must be handled many times between the start and finish of its journey through the shop. Larger work is piled on the shop floor and must be moved from here to other departments either by hand or by being loaded on trucks and again unloaded at the other end.

Heavy machines are moved from place to place by rollers under the skids, coupled with a liberal use of crowbars and profanity. This is particularly true of machinery salesrooms, many of which sell cranes and conveying machinery. The cost of loading and unloading machines from drays in the usual way is a much larger item than we might be willing to believe if we looked into the matter carefully.

Some shops where this has been considered to some extent, make it a point to have the product of any machine placed directly on a substantial shop truck so that it can go to the next department without further handling or delay. This is done either in boxes or in racks, according to the nature of the work, but in either case there is a distinct gain in time over the other method. There is also likely to be much

* Abstract of paper presented before the Congress of Engineering at the Fifth Anniversary of the dedicating of the Chapter of the Massachusetts Institute of Technology.

** Vice President, Allis Chalmers Co., Milwaukee, Wis.

less damage to the work itself, and, besides reducing the actual handling cost, it avoids delay between departments which is not only exasperating but also expensive.—American Machinist.

AN OBJECT LESSON IN EFFICIENCY.*

Reporting the working out of one of the most notable examples in this country of "Scientific Management" according to the "Taylor system," Wilfrid Lewis, president of the Tabor Mfg. Co. of Philadelphia, described the state of his company "before and after," and gave many details of the transition from failure to success. Mr. Lewis in describing his entrance into the Tabor Company eleven years ago, said: "I was advised by my well-wishers to keep an open shop and keep down the number of clerks or non-producers. Success I was told depended upon the ratio of producers to non-producers in any well managed concern. Draftsmen were recognized as a necessary evil, the fewer of them the better, and one good superintendent to lay out the work and keep it moving through the shop, was considered quite enough. In fact, to the casual observer, we had hardly enough work to keep a good man busy and we did not appreciate the need of better shop management until our growing business began to show increasing losses. Before we were aware of any dissatisfaction and within a year of the opening of our shop, we were surprised by a general strike for higher wages and shorter hours. Our unguardedness or lack of management had encouraged our men to combine against us and make unreasonable demands. We were then paying them more than they earned and they insisted upon having still more, which simply meant ruin to the company in a short time. Our strike was compromised by the concession of shorter hours at the same pay, the men agreeing to turn out the same amount of work per day. There was no difficulty about their doing this, and for a time I believe they kept their promise, but a day's work was then with us as it is now with nearly the whole world of industry, a variable and indefinite result for a given expenditure of time or money. We had no standard by which a proper day's work could be fixed except the very shaky and misleading one of the best that had been done before, and having as we were now well aware, an organized resistance against any increase in out-put or efficiency to meet, the outlook for the company was not encouraging. At the same time we knew that machines had been built by others for less than they were costing us, and we felt confident that a way could be found out of our difficulties.

The firm took up the Taylor system; the launching of the new order being immediately in the hands of Barth, one of Taylor's assistants at Bethlehem. The directors of the company soon split over the issue, and the anti-Taylor members finally solved part of the problem by withdrawing from the company. Mr. Barth was obliged, as he proceeded in his work, to call for more and more assistance and as new men were added to our planning department, the cost of the new system began to draw so heavily upon our resources that for a year or two we seemed to be actually losing ground, and we certainly would have been obliged to suspend but for the grit and determination of Dr. Taylor, who had the courage of his convictions and carried us through the storm, which culminated in the resignation and withdrawal of the opposing forces.

From this time forward conditions began to improve, and the work begun by Barth and continued by Hathaway, who is now vice-president of our company, began to bear fruit. It was not long before we ceased to lose money, broke even and began to gain. A better spirit prevailed, better wages were earned, and production increased so rapidly that I was lost in astonishment at the potency of the engine gratuitously placed in my hands through the good offices of my life-long friend. We had in effect been installing at great expense a new and wonderful means for increasing the efficiency of labor, in the benefits of which the workman himself shared, and we have to-day an organization second I believe to none in its loyalty, efficiency and steadfastness of purpose.

In 1910 The Tabor Mfg. Co. turned out 2½ times as much value in finished product as it ever did under the old regime with the same force. Formerly for every ten men engaged as producers or "chipmakers," as Dodge defines them, we had not more than one man connected with the shop as a non-producer. Now we have fewer men at machines with three times as many non-producers turning out practically three times as much work, because prices are lower to-day than they were five or six years ago, and 2½ times the value means about three times the product.

We pay better wages for fuller and better results performed in a definite way, and yet there is no driving in the ordinary sense of the word. The tasks assigned to the workmen are easily within their ability to perform, and when new work is given out as occasionally happens at day rates, before the time on the job has been set, nobody wants to take it because there is no bonus attached for its quick and accurate performance.

*Presented before the Congress of Technology at the Fiftieth Anniversary of the Granting of the Charter of the Massachusetts Institute of Technology.

HOW TO SAVE $1,000,000.

The part "little things" play in the operation of a great railroad is well brought out in a circular recently issued to the employes of a large railroad system. The circular states: "You are one of about 50,000 employes. Can you save 5 cents a day for the company? That is only $1.50 a month. A few spikes, bolts, etc., saved, or material not replaced until full use has been obtained, will turn the trick for track men. Train and yard crews watching every move and not wasting their time will do their share. Enginemen can easily use a few less shovefuls of coal and make a better showing. Station and telegraph employes by being prompt on the wires, and careful handling of freight will save delay to trains and reduce claims. Office men can reduce unnecessary wires and correspondence, save stationery and postage. Shop men have many ways of saving time and materials. Everyone can help and some can help others. A small saving by each employe spells prosperity. Prosperity hires more men and pays better wages than hard times."

THE GENERAL SUPPLY CO., OF CANADA, LIMITED.

The General Supply Co., of Canada, 115 to 125 Adelaide street west, Toronto, with head office at Ottawa, Ont., and western branch at Winnipeg, Man., is making rapid progress in the extension and increase of its business among the large and small manufacturing corporations and companies throughout the Dominion.

Mr. C. R. Medland, Toronto branch manager, informed our representative that since opening up at the beginning of the year, their sales have exceeded the highest expectations. Their staff has grown from two to twelve, and not the least important addition has been that of A. E. Juhler, late sales representative of London Machine Tool Co. Mr. Juhler takes care of the machine tool sales, and his former experience in this direction makes him a valuable acquisition. Mr. T. C. MacDonald looks after the smaller supplies, and he, too, is a thoroughly experienced man in this department.

No expense has been spared in securing the most competent men to manage the various departments, and every care has been taken in the selection of a full and reliable line of engineers' and general manufacturers' supplies. In addition to a steady demand for moderate daily quantities, Mr. Medland reports contracts for installations of the complete equipment for various new mills and factories.

FOUNDRY PRACTICE AND EQUIPMENT

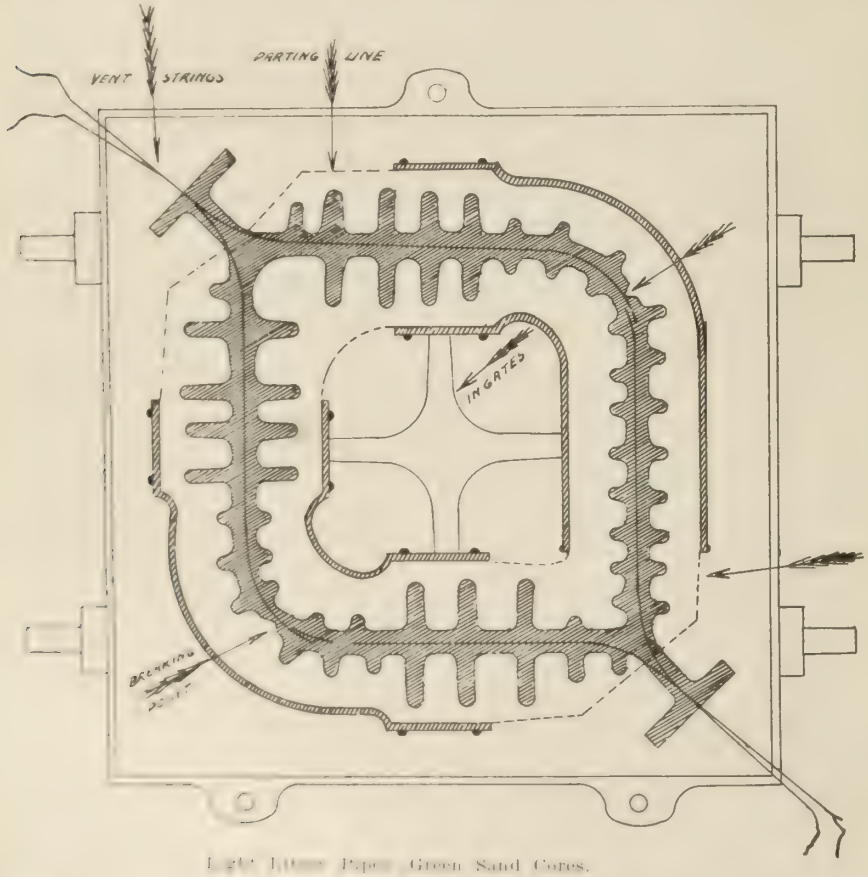
Practical Articles for Canadian Foundrymen and Pattern Makers, and News of Foundrymen's and Allied Associations. Contributions Invited.

LIGHT ELBOW PIPES — GREEN SAND CORES.

By John H. Eastham.

Light elbow and other connections for heating apparatus or similar purposes can be made a paying line where a steady sale is possible, by a small initial outlay on patterns and rigging. Well-fitted iron boxes are advisable, with a minimum of play in pins.

Patterns should be made in halves, and of metal, with short dowel pins to avoid twisted castings. A good open grade of sand is essential to release vents from cores easily and prevent risk of loss through blown castings.



On a good flat turnover board, lay core bar with prods upwards; cover this with bottom halves of patterns, ram up stiff and turn over a solid way. Cut out bottom joint from ends of patterns to shape of core bar allowing a little rounding ready, and line up with wet parting sand in level of box edge. Lay a little sand in patterns and place core bar, (dry sanded) into position. Tap or rub core bar down as low as possible. To secure clean lift when removing cope, and tap up to pull pins.

Place vent strings as shown in sketch; slightly damp top halves of patterns, ram them hard full of sand, strickle off level, cut out ridges for vents, and turn them over smartly on to bottom halves. Make joint sloping up to ends of patterns, and wet parting sand up to top.

To ensure clean lift, ram up cope and lift off with one screw in each pattern to remove them from core at same time. Cut away clear, T handles on core bar and take out core, placing it on soft sand bed or on two weights in the case of larger size pipes.

When pipes exceed $\frac{1}{2}$-inch in thickness, a few shavings burnt under core to skin dry it a little is beneficial; but if a good sized vent is used, this is not absolutely necessary. Draw bottom halves of patterns, and cut runners as shown in sketch, no risers being required. Little or no finishing should be needed. Dust a little charcoal blacking on mold, put core back into place, and close.

Hot iron and clean skimming are essential to obtain good results, and a percentage of 1 part coal dust to 7 parts sand in cores, will assist air to escape and also give smooth surface to inside of pipes. When shaking out, a few taps will clear core and core bar from castings; a single blow being sufficient to break core iron, owing to weak place shown at bend of elbow. By this system castings are obtained true to pattern, and cost of fettling considerably reduced. With a little practice a boy of 17 years will turn out a surprising quantity per day. When box bars follow patterns, no gaggers or soldiers are needed; the main points to remember being, not to work sand too damp, and to employ a good open vent in every instance.

Light Elbow Pipes, Green Sand Cores.

HARDENING AND MIXTURE FOR CAST IRON.

By William Barrow, Montreal.

The usual method of hardening a small quantity of iron is to sift powdered ferro-manganese into it as it comes from the cupola spout. The hardening effect is not great, but it gives a closer grain to the iron. To ensure a harder mixture, 10 to 25 per cent. of car wheel scrap should be added to the charge in the cupola. A small quantity of sulphur in the ladle produces white iron, but usually too hard for most purposes. If you find that silicon is high in your mixture, try one part sulphur to 45 parts iron. The result will be a hard but by no means white iron. Most foundrymen have a dislike to the use of sulphur, but under the above conditions it will prove beneficial. It may be noted that cast iron should contain few impurities, especially free carbon which interrupts the crystalline continuity of its structure.

Strength of Cast Iron.

Generally speaking, cast iron has an ultimate tensile strength of 18,000 to 21,000 pounds per sq. inch., and is not losing so much ground as people think, because it is possible for a foundry to turn out an iron having a tensile strength of 34,000 to 35,000 pounds per sq. inch with a density of 7.28. This goes to show that the material is capable of competing with steel in many ways. The mistake most often made when high quality castings are required, is that of mixing high and low silicon irons. For strength and durability, the silicon and carbon should be both as low as possible; the hardness being taken care of by mixture of sulphur, manganese and phosphorus. Occasion arises to say, why cannot silicon be used to give fluidity, if silicon is the key to success in producing this robust material?

We reply that the fluidity caused by silicon is only great while it lasts, being narrow in range and rapid in solidification.

To obtain good grade castings then, the iron should be low both in silicon and carbon, but have a fair measure of manganese and phosphorus. Sulphur may be of higher percentage than the general limit allowed by the analyst. Highly satisfactory results are obtained from the following :

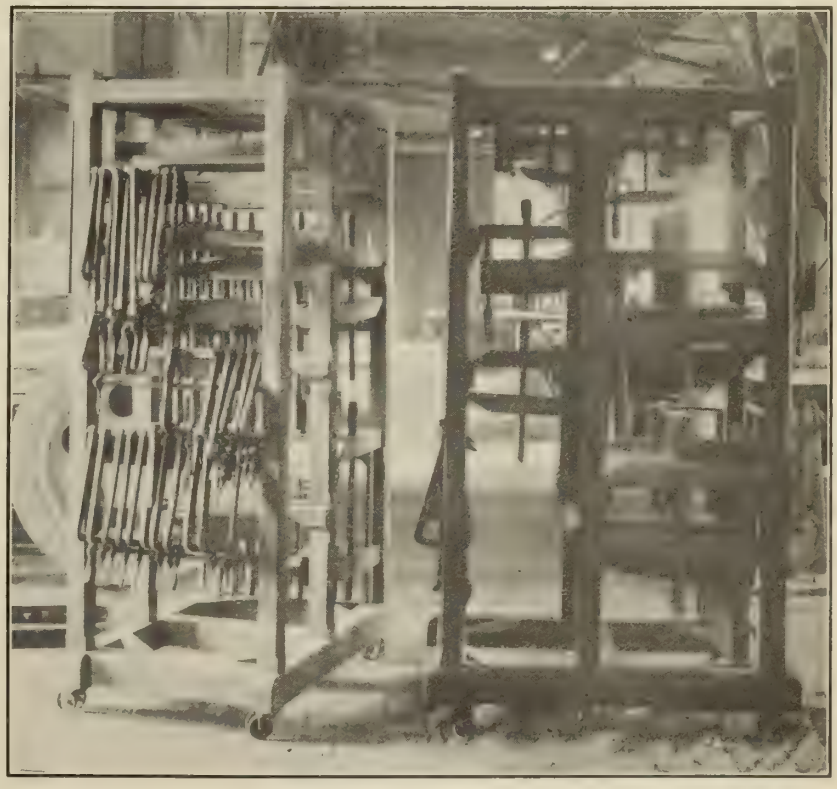
Bearcliffe Pig ... ...22 per cent.
Cold Blast ... ...27 per cent.
Selected Gray Scrap .....23 per cent.
Frodair Pig ....28 per cent.

The above irons are all melted in Europe. Bearcliffe is a rather tough iron of good class Hematite and carries about 1 per cent. of silicon, about the same of carbon and is low in phosphorus, sulphur and manganese. Frodair is a dark iron carrying low silicon and extra low carbon, but melting hot and fluid by reason of a fairly high percentage of manganese and phosphorus Its sulphur ranges from 0.08 to 0.10 The scrap iron was not analysed but was judged to be low in silicon and carbon, and medium in phosphorus and manganese.

In the mixture, 28 per cent Frodair has been taken to make sure of the head and fluidity of metal. As a really low carbon basis for a specification, 22 per cent. Bearcliffe will keep phosphorus within safe limits and ensure fluidity with its manganese. Cold blast is added to return carbon which has been lowered by Bearcliffe. It also serves to keep sulphur within safe limits, and guards against extreme hardness. The two latter secure strength and toughness in the mixture. It will be noted that all have about equual silicon, consequently it will be seen that for many purposes, cast iron will answer for steel. The all important point is to have a rapid and hot melt.

Cupola Blast.

Many foundries suffer from insufficient blast, and thereby fail to obtain scheduled capacity. This is a fault capable of being remedied. Allow 33,000 cubic feet of air for every ton of metal melted, and figure the quantity of air per minute the fan should deliver in proportion to the limited capacity of the cupola ; then install a fan that will produce and convey easily this amount of blast to the furnace, taking care that wind box and tuyeres are of sufficient area. A pressure gauge should be placed on the wind pipe where it joins the fan casing, to determine the amount of air being delivered. A certain amount of loss will result from friction in the pipes and attachments.



Better results in density and strength will be got when the iron is cast hot, as the greater the fluidity the more complete will be the escape of gases. Again the hotter the poured iron, the more rapid the cooling process ; because the temperature will vary over a wider range in a given time.

PATTERNMAKER'S HANDSCREW RACK.

By H. J. McCaslin.

A common sight in pattern shops is to see hand screws on the wall, on and under the benches, on the floor, and, in fact, everywhere there happens a corner to throw them. Every patternmaker knows that unless a place is provided, handscrews have a peculiar way of getting mixed up with everything else.

Herewith is shown two racks that have been in use for some years. With two of them placed near each end of the shop, and with strict orders that all clamps must be returned to place immediately upon their removal from work, very little of the aforementioned trouble was experienced. A great deal of the pattermakers' time was saved for they knew where to look for the clamps when they were required for a job.

Patternmakers' Handscrew Rack.

The racks were mounted upon casters and can therefore be rolled to any part of the shop. This was found to be a convenient feature when glueing up large stock, or glueing up segmental work upon the face plate when clamps are required at intervals. It will be seen that the central part of the rack is designed to receive various size wood clamps, while each end is fitted with a bar for iron clamps.

NEED OF VENTILATION FOR BRASS FOUNDRIES.

A commission on occupational diseases appointed by the Illinois legislature, made a comprehensive report in January. Its investigations covered lead poisoning, brass poisoning, carbon monoxide poisoning, the effect of compressed and so-called work poisons in general. In the brass trade, the workman may be poisoned by fumes, but these are controllable ; and the finding of the studies in this detail is that brass founders' ague is preventable. The poorer varieties of brass have of course a large proportion of zinc. Brass founders' ague, it is believed, is caused by the sublimation products of zinc, and therefore the foundries making the cheaper grades are more dangerous to work in than those making better grades. In large foundries with good ventilation, either natural or artificial, brass chills are practically never seen. As for actual conditions in Chicago, only 4 of the 89 foundries visited could be classed as well equipped and free from trade sickness ; 63 were acknowledged as the centres of trade sickness ; 7 more were suspected of being equally bad.

A physical examination of 187 men, representing 78 foundries, showed that 146 complained of some trade sickness, 15 of brass chills. As brass founders handle lead, arsenic, antimony, phosphorus, and the cyanides, chills are not the only form of illness to which they are subject.

Foundrymen's Convention and Exhibit at Pittsburg

Whether Looked at from a Fraternal, Educational or Business Point of View, the Convention and Exhibit of the American Foundrymen's Association and Allied Bodies Must Rank as the Most Largely Attended, Most Extensively Progressive in its Scope, and Most Successful in its Conduct and Results, of the Many Previously Held.

THE sixteenth annual convention of the American Foundrymens' Association, its allied bodies the American Brass Founders' Association, the Associated Foundry Foremen and Exhibitors' Association was held in the Pittsburgh Exposition Buildings from May 23rd to 26th inclusive. On account of the meetings of the American Society of Mechanical Engineers following immediately thereafter, the exhibit remained open and in operation until June first.

At no previous meeting was such a wide range of machinery exhibited as at this, and a most gratifying feature of the exhibits this year is that practically all of them were installed and in operation when the doors were opened. A very large number of moulding machines were shown, and as indicative of the development in this direction, there was an increased number and variety of jolt ramming machines on exhibition. One new type, attracting much attention, was electrically driven. Core making machines of various kinds, were also plentiful.

The professional sessions opened in the auditorium of the Exposition buildings, Major J. T. Speer presiding. Cordial addresses of welcome were given by representatives of the city of Pittsburg and the chamber of commerce, to which as cordial a response was made by A. D Howard, vice-president of the American Foundrymen's Association. Major Speer in his brief annual address, pointed out that great strides had been made in the past few years in the science and art of founding as a result of co-operation and interchange of ideas among foundrymen. He also commented on the prevailing unsatisfactory business conditions, but expressed firm belief in an early return of good times.

Dr. Richard Moldenke, secretary of the American Foundrymen's Association, in his annual report, said that for the first time in the history of the organization, the transactions have been sent to members hip in bound form. He said that much progress has been made in the development of the permanent mold and in continuous melting practice. His report showed a total membership of 692 and a balance in the treasury of $1,541.95.

N. K. B. Patch in his report as president of the American Brass Founders' Association laid emphasis on the fact that the appointment of an official chemist had been made by them, and that satisfactory results and returns might be confidently looked for in the future. The report of Secretary Corse showed a gain in membership, which now amounts to 287, and a cash balance of $94.88 after disbursements during the year of $1,386.59.

Regret was expressed at having to record the recent deaths of two prominent members of the Exhibitors' Association, in the persons of W. W. Sly, president of the W. W. Sly Mfg. Co., Cleveland, O., and A. N. Spencer, vice-president of the Olivery Machinery Co., Grand Rapids, Mich., both of whom had made arrangements to attend the convention this year as usual. Resolutions of condolence were ordered to be drafted, for sending to the bereaved families and for entry in the minutes of the association.

The reading of papers enumerated in our previous issue and to be published in more or less detail in future issues of Canadian Machinery and Canadian Foundryman, formed an interesting and important feature of each day's proceedings of the various associations. In this connection it is worthy of note that those engaged in steel foundry work, had

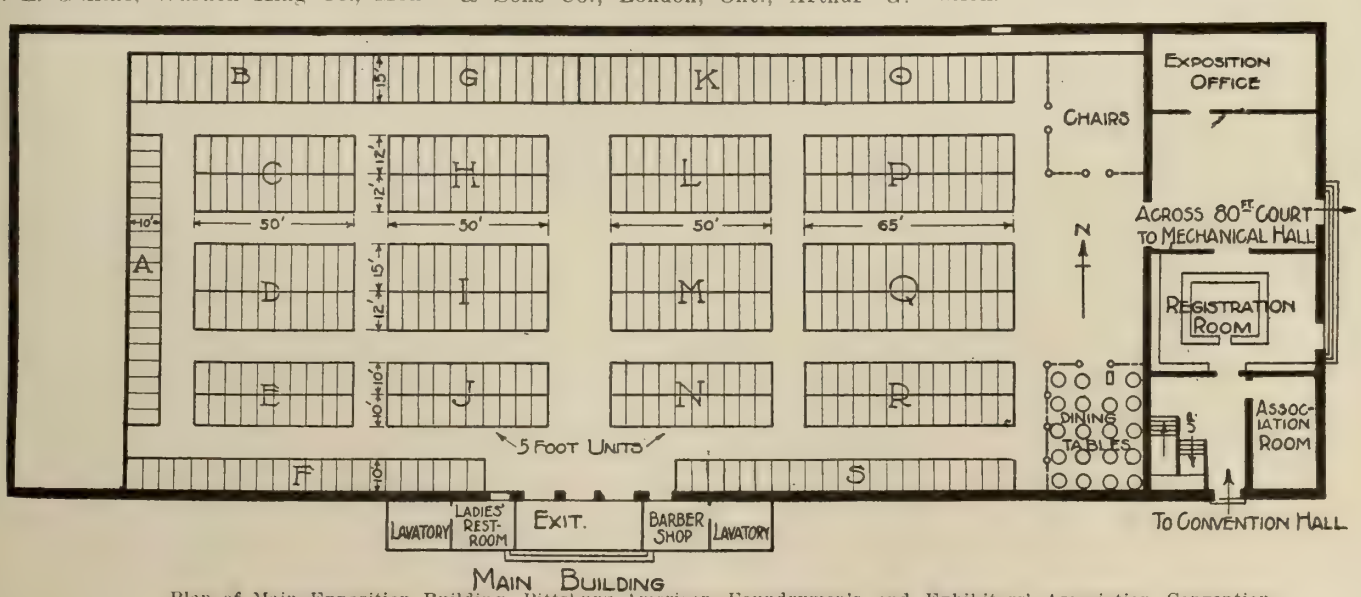
Exposition Buildings, Pittsburg. American Foundrymen's and Exhibitors' Association Convention.

for the first time a session devoted entirely to that particular department.

Among the works' visits arranged and fully taken advantage of by the delegates were those of the Westinghouse Air Brake Co., the Homestead Steel Works and the Maesta Machine Co. The recreative, amusement and social side of the convention was provided for in the big league ball game between Pittsburg and Cincinnati ball teams, the vaudeville entertainment given by the Exhibitors' Association, the dinner given the Associated Foundry Foremen by the Pittsburg Foundry Foremen's Association, and the open subscription dinner given at the Fort Pitt Hotel.

While much attention was paid to the requirements of the male delegates, the ladies attending were in no way neglected. In addition to their presence at the vaudeville entertainment, an automobile ride with dinner at the Country Club, and visits to the Carnegie Institute, Margaret Morrison (Carnegie) School and Phipps Conservatory, formed part of their programme.

A gratifying feature was the large and representative body of delegates from Canada, bent on the idea of keeping posted in the latest developments of the foundry field, and who have carried back to their respective shops and put into effect, the good things seen and noted. Among those Canadian foundrymen present we noticed:—J. A. Agnew, Standard Sanitary Mfg. Co., Toronto, Ont.; G. T. Baguley, Dominion Stove Foundry Co., Toronto, Ont.; T. B. Bennett, D. E. Maxwell & Sons, St. Mary's, Ont.; Peter Bain, Canadian Foundryman, Toronto, Ont.; S. L. Chapman, Ont. Wind Engine & Pump Co., Toronto Ont.; S. B. Chadsey, Massey-Harris Co., Toronto, Ont.; H. W. Donald, Standard Sanitary Mfg. Co., Toronto, Ont.; J. H. Fryer, Galt Malleable Iron Company, Galt, Ont.; H. Goodes, John Inglis Co., Toronto, Ont.; H. L. Gulline, Warden King Co., Montreal, Que.; B. Geary Co., American Abell Co., Toronto, Ont.; W. R. Glasgow, Canadian Steel Foundries, Welland, Ont.; H. Hertfelder, Dodge Mfg. Co., Toronto, Ont.; A. R. Hockin, Taylor-Forbes, Guelph, Ont.; W. G. Harris, Canada Metal Co., Ltd., Toronto, Ont.; H. V. Hamilton, The Steel Co. of Canada, Hamilton, Ont.; Thos Jenkins. Dodge Mfg. Co., Toronto, Ont.; W. A. Jackson, Steel & Radiator Co., Ltd., Toronto, Ont.; Matt. Kennedy, Jr., Wm. Kennedy & Sons, Ltd., Owen Sound, Ont.; M. Kelly, Western Foundry Co., Wingham, Ont.; H. O. Kerr, Kerr Engine Co., Ltd., Walkerville, Ont.; A. Knight, Canadian Northern R.R., Winnipeg, Man.; P. Michael, The Dominion Radiator Co., Toronto, Canada; R. R. Mitchell, The Robert Mitchell Co. Ltd., Montreal, Canada; J. K. Moffat, The Moffat Stove Co., Weston, Ont.; J. R. Meadowcroft, The Garth Co., Montreal, Canada; A. C. Morris, Ontario Wind Engine & Pump Co., Toronto, Canada; J. McLaren, Findley Bros., Carleton Place, Ont.; A. J. Oliver, The R. McDougal Co., Galt Canada; J. R. Phillips, Pease Foundry Co., New Toronto, Ontario; Chas. B. Phinn, Canadian Westinghouse, Canada; J. R. Porter, Empire Mfg. Co. Ltd., London, Ont.: A. J. Palmer, Empire Mfg. Co. Ltd., London, Ont.; N. K. B. Patch, Lumen Bearing Co., West Toronto, Ont.; E. B. Rouse, Warden King, Montreal; James Shand, Dodge Mfg. Co., Toronto, Can.; Robt. Saville, Taylor-Forbes Co., Canada; G. D. Smith, Canadian Steel Foundry Co., Montreal, Que.; G. Service, Steel & Radiator Ltd., Toronto, Canada; H. V. Tyrell, Canadian Foundryman, Toronto, Can.; T. W. Turner, Allis-Chalmers-Bullock, Montreal; Sam H. Todd, Todd-Dominion Radiator Co., Toronto, Canada; A. H. Tallman, Tallman Brass & Metallic, Hamilton, Can.; A. M. Tait, Wortman & Ward Co., London, Ont.; Frank White, The Geo. White & Sons Co., London, Ont.; Arthur G. White, The Geo. White & Sons Company, London, Ont.; Joseph Wright, Dominion Radiator Co., Toronto, Canada; Geo. Woods, Wm. Kennedy & Sons, Ltd., Owen Sound, Ont.; Geo. H. Weaver, Dominion Foundry Supply Co., Montreal, Can.



Convention Closing.

Buffalo was chosen unanimously as the next convention city, all the other cities having withdrawn from the contest.

The American Foundrymen's Association elected the following officers: President, J. T. Speer, Pittsburg; secretary and treasurer, Dr. Frederick Moldenke, Watchung, N. J.; Vice-Presidents, F. V. Miles, Buffalo; Walter Wood, Philadelphia; A. E. Howell, Nashville, Tenn.; R. C. Bull, Granite City, Ill.; T. W. Sheriff, Milwaukee; D. R. Lombard, Augusta, Ga.; S. B. Chadsey, Toronto, Canada.

Officers elected by the American Brass Founders' Association are: President, L. W. Olsen, Mansfield, O.; secretary and treasurer, William N. Corse, Buffalo, N. Y. Vice-presidents, for New York and New Jersey, John S. Thompson, Orford, N. J.; rolling mill district, R. T. Roberts, Hastings on the Hudson, N. Y.; New England district, P. F. Augenbraum, Stamford, Conn.; Pennsylvania district, G. H. Clamer, Philadelphia; Chicago district, R. C. Faunt, Chicago; Michigan district, H. W. Gillette, Detroit; Southern district, J. S. Sharp, Chattanooga, Penn.; Ontario and Western provinces, N. K. B. Patch, Toronto, Canada; Quebec and Eastern provinces, R. K. Mitchell, Montreal, Quebec.

The Associated Foundry Foremen closed their convention by electing the following officers: Robert B. Thompson, Buffalo, president; William H. Woods, Pittsburgh, vice-president; Hugh McPhee, of Tarrytown, N. Y., secretary-treasurer. Mr. Woods is the president of the Pittsburgh Foundrymen's Association.

Plan of Main Exposition Building, Pittsburg, American Foundrymen's and Exhibitors' Association Convention.

INDUSTRIAL AND CONSTRUCTION NEWS

Establishment or Enlargement of Factories, Mills, Power Plants, Etc.; Construction of Railways, Bridges, Etc.; Municipal Undertakings; Mining News.

Foundry and Machine Shop.

TORONTO ONT. J. F. Brown has retired from the metal furniture business and will devote his entire attention to the Ontario Brass & Copper Co., of New Toronto, of which he is owner and president. An extensive addition will be made to the plant.

MONTREAL, QUE. It is announced that the contract for the dry dock here has been definitely awarded to Vickers' Sons & Maxim. The subsidy to be paid to the contractors by the Federal Government will be at the rate of 4½ per cent. on a capital outlay of $3,000,000 for thirty eight years. The drydock will have a lifting capacity of 25,000 tons, sufficient to accommodate any vessel likely to use the St. Lawrence route for many years to come.

OTTAWA ONT. The Public Works Department will call for tenders within a few days for very extensive harbor works at St. John, totalling in aggregate cost probably four or five millions. There will be a dry dock built with an extensive ship repairing plant in connection. Docks will be built providing three berths for the G.T.P. ocean steamship service. Several companies backed by British capital are ready to tender for the whole of the proposed works. The department is also calling for tenders for an extension of the wharf at Champlain market, Quebec, in connection with the National Transcontinental Railway terminals.

KINGSTON, ONT. The Canadian Locomotive Co., of Kingston, has sold out to an English syndicate composed chiefly, it is understood of Lord Glenconner Darlborough Pryor, J. Leigh Wood, and F.R.S. Balfour, who recently visited Kingston to inspect the works. The price paid is said to be large. At present, the capital stock of the company is $500,000. This will be substantially increased. The company has a capacity of three locomotives a week.

QUEBEC, QUE.—The greatest railway workshops in Canada outside of Winnipeg will be erected within a few miles of Quebec City in connection with the Grand Trunk Pacific, according to plans presented. Tenders for the shops will be called for as soon as details are arranged.

VANCOUVER, B.C.—An English company, with a Vancouver board of directors, will, in a few days, be registered with a capital of $20,000,000 to start and carry on business at Pitt Meadows.

The object of the company is to acquire large ore and coal lands, the latter on Vancouver Island and a site on which the necessary works will be erected. Blast and open hearth steel furnaces, and rolling mills, are to be part of the plant. W. Owen, M. E., of London, England, is handling the project. The plant and machinery are to be brought from Europe and will consist of blast furnaces, open hearth steel furnaces and rolling mills of a very large scale and there will also be foundry and engineering shops for renewals and repairs. At least 2,000 men are to be employed. The full capacity of the works will be 1,000 tons a day, and the company estimate on 250,000 tons a year in finished products. The conservative estimate would still keep only busy for an additional 50,000 tons.

ORILLIA ONT. The Tudhope Motor Co. recently purchased the Orillia Foundry building from W. Beal. Oxy-Blowpipes mixed with oxygen, produce a terrific heat and melts any metal. Two metal pieces can be welded together without breaking and without the use of another metal. The outfit is portable and light and can be carried from room to room or from shop to shop as required. It is used to operate for welding brazing soldering etc. and supplied to more other than nothing simply heating to full cases.

PETERBORO' ONT. At the recent fire breaking out in the cut pump works here $20,000 damage was done. The stock are now a total wreck.

PEMBROKE ONT. In an effort to get the C.N.R. shops to locate here the Board of Trade has appointed a committee to interview the railway officials and point out the town's advantages.

The Oliver Plow Works, Hamilton, Ont., have awarded to H. Christman & Co., of South Bend, Ind., contracts for two more large buildings. One is the paint building, 64 by 350 feet, three storeys high, which will be reinforced concrete, costing about $100,000, and an office building, two storeys and basement, 46 by 101, costing $30,000. As soon as these are completed, two foundry buildings, an immense warehouse and a forge shop will be erected.

INGERSOLL, ONT.—The John Morrow Screw, Limited, are preparing to expend $150,000 on their plant here.

OTTAWA, ONT.—Hon. Mr. Pugsley has given notice of a resolution calling for the ratification of an agreement between the Government and the Collingwood Shipbuilding Co., for the construction of a dry-dock at Collingwood. The agreement provides that the Government may pay the company a subsidy of three per cent. for twenty years upon $306,965, the cost of the dry-dock.

PRESTON, ONT.—The Car & Coach Co. are building another erecting shop, and what is now known as No. 1 shop will be converted into a mill and machine shop.

VANCOUVER, B.C.—The Pacific Marine Engineering Co. have completed a new factory and are manufacturing power and sail yachts of all types up to 90 feet. The mechanical equipment is thoroughly up-to-date. A large number of skilled mechanics and machinists are employed by the firm, which promises to be an important factor in the boat-building industry.

REGINA, SASK.—The Farmers' Steel and Wire Co. are about ready to start manufacturing farm, field and ornamental fences. It is their intention to enlarge the present plant if business warrants, and also start a bedspring factory.

GUELPH, ONT.—The rumor that the Page-Hersey Co. will move their Guelph plant to Welland is evidently erroneous. At present, they are erecting two large storehouses and are installing new machinery.

VANCOUVER, B.C.—An early start will be made on the construction of the big, 15,000-ton steel floating dry-dock to be located near Roche Point at the entrance to the North Arm of the Inlet. Cable advices have been received from the firm of prominent capitalists who are supplying the capital required for the local dry-dock, which will be built on the Tyne and shipped out here, to the effect that these capitalists had taken over the assets of the old Vancouver Dry-dock Co., organized some years ago. In taking over the old company the promoters had increased its capital to $1,500,000. Arrangements have been made by the organized company to commence operations in time to receive the Dominion Government subsidy granted some time ago, for the construction of a dry-dock of the second class as approved and suitable for naval requirements.

TORONTO, ONT.—The Lake Superior Corporation has formed another company under the name of The Superior Rolling Stock Co., Limited. The new company, as its name indicates, will manufacture locomotives, cars, rolling stock, etc. The authorized capitalization is one million dollars, and the provisional directors include Thomas Gibson, general counsel for the corporation.

PORT ARTHUR, ONT. The Port Arthur Wagon Works Co. announce that building operations will at once be commenced for their big plant here which will turn out 250 wagons per week.

CHATHAM, N.B.—Miller's Foundry has been moved to make room for railroad purposes. Both the machine shop and moulding shop have been re-arranged.

TORONTO, ONT.—An American firm, the York Safe & Lock Co., of York, Pa., has secured the contract for the erection of the vaults in the new million dollar Bank of Toronto Building. This means that Canadian vault builders and workmen have lost a contract amounting to about $150,000.

ALBERNI, B.C.—A survey has been made for the E. & N. Railway's roundhouse and machine shop to be located on Lupsie Cupsie Point, near here.

SAULT STE. MARIE, ONT. In a disastrous fire at the charcoal plant of the Standard Chemical Iron & Lumber Co., Steelton, the entire retort plant was destroyed and is a total loss. The damage will reach many thousands, covered by insurance. It will be re-built.

PORT ARTHUR, ONT.—J. S. Small, of Detroit, is conferring with the civic industrial committee with the view of establishing an automobile factory here.

MAHONE, N.S.—A. E. Ernst, son of E. A. Ernst, who has held the position of foreman with the Truro Machine Company for the past year, has severed his connection with that firm, contemplating a trip west. Mr. Ernst is being urged to remain here and open up a machine shop.

MONTREAL, QUE.—Losses by smoke and water estimated at $85,000, fully covered by insurance, were caused by a fire in a building on Wellington Street, occupied by the Canada Machinery Co., the Ives Modern Bedstead Co., and the Factory Waste and Metal Co., and the Canada Office Furniture Co.

WELLAND, ONT.—At the annual meeting of the Board of Directors of Canadian Billings-Spencer Works, it was decided to make preparation for the construction of an addition to the present factory buildings. The new building will be two storeys in height, of concrete construction and 100x50 feet in size.

WELLAND, ONT.—The Dominion Metals, Ltd., of Toronto, will build a thoroughly up-to-date silver and gold smelting and refining plant here.

NORTH BAY, ONT.—M. Davey has leased the Nipissing Foundry & Machine Co. for a term of years and is now in possession. He has moved his wire works to the foundry.

HESPELER, ONT.—The A. B. Jardine Co. are building a large moulding shop, 60x60. This is the second time this year that this company has been forced to enlarge its plant.

AMHERST, N.S.—The Canada Car Co., have made arrangements to re-build their works here. The new building will be of concrete and steel. The freight car department, representing 90 per cent. of the output and the wages, will remain closed until the new shops are completed.

TORONTO, ONT.—The Maritime Nail Works at St. John, N.B., has been disposed of by R. L. Johnston to Toronto interests for about $200,000, the transfer to be made June 1. Definite announcement as to the intentions of the new owners is expected at any time.

WELLAND, ONT.—The Imperial Manufacturing Co, manufacturers of hardware, of Warren, Pa., will locate a branch factory here.

TORONTO, ONT.—The Hupp Motor Car Co., of Detroit, are preparing to enter the Canadian field. They will manufacture their cars in Canada and establish a new selling price. Their car now sells for $900 in Detroit.

QUEBEC, QUE.—W. H. Wiggs has secured a site from the C.N.R. and will erect a large warehouse for his business, the Mechanics' Supply Co. He will carry a large stock of iron pipe, radiators and "Daisy" boilers.

MONTREAL, QUE.—The McArthur, Perks Co., of Ottawa, has been awarded a contract to build four concrete docks at Havana by the Port of Havana Docks Co., of which Sir William Van Horne is president. The Ottawa company is the one formed by Sir Robert Perks, and the contract it has secured at Havana amounts to about $6,000,000.

LONDON, ONT.—The McClary Company are planning a big extension to their East End works here. They have taken out a permit for an $18,000 cement building for manufacturing purposes.

PORCUPINE, ONT.—Fire did $70,000 damage to the plant on the Hollinger property here recently.

FREDERICTON, N.B.—The New Brunswick Foundry was practically wiped out by fire recently. The loss was upwards of $50,000, including the patterns which had accumulated in 40 years operation of the plant. About $15,000 insurance was carried, largely in the Atlas Co. The matter of re-building is as yet, undecided.

VANCOUVER, B.C.—The Munro Steel & Wire Works, of Winnipeg, will build a plant here to cost approximately $50,000.

CLARKSBURG, ONT.—J. L. Lake has leased the Clarkesburg Foundry and Machine Shop and is now in charge.

This Large New Warehouse in Toronto

has recently been added to our system of General Supply warehouses and sales agencies.

The opening of this warehouse will enable us to give our customers in this district the same efficient service enjoyed by our customers in the vicinity of our Ottawa and Winnipeg houses.

A staff of efficient salesmen—each man a specialist in his line—has been engaged to look after those in need of advice as to the best equipment.

THE GENERAL SUPPLY LINE

is up-to-date, and includes the product of some of the best known and most progressive makers of machine shop and general factory equipment. The list speaks for itself:—

LONDON MACHINE TOOL CO.—Machine Tools.
R. K. LeBLOND CO—Milling Machines, Grinders and Lathes.
JOHN STEPTOE SHAPER CO.—Shapers.
FAY & SCOTT—Lathes.
MUELLER MACHINE TOOL CO.—Radial Drills.
H. G. BARR—Sensitive Drills.
STANDARD PRESSED STEEL CO.—Steel Hangers.
CLEVELAND TWIST DRILL CO.
SOUTH BEND MACHINE TOOL CO.—Lathes.
HISEY-WOLF MACHINE CO.—Electric Drills.
AMERICAN PULLEY CO.—Pressed Steel Pulleys.
BEARDMORE BELTING CO.
VI-BALATA BELTING.

If you have not tried "General Supply Service" let us have your enquiry the next time you are in the market. We make a specialty of filling telegraph or phone orders.

COME IN AND SEE OUR LARGE STOCK OF PRESSED STEEL PULLEYS AND HANGERS.

If you've had trouble with crucibles because of severe melting conditions, try a sample order of

DIXON'S CRUCIBLES

and watch the results. We welcome an opportunity of this kind—it proves the stuff of which Dixon's Crucibles are made.

Descriptive Booklet No. 223-A free.

JOSEPH DIXON CRUCIBLE COMPANY
JERSEY CITY, ... N.J., U.S.A.

VANCOUVER, B.C.—The Otis Elevator Co. are building an office and warehouse here at a cost of $200,000.

OWEN SOUND, ONT.—The citizens carried a by-law granting the C. S. Lloyd & Co., of Toronto, a loan of $25,000 at 4½% interest to erect a factory here for the manufacture of children's carriages and wagons, and steel wheels for various kinds of vehicles.

PETERBORO', ONT.—The Model Foundry and Pump Works have commenced operations.

PORT HOPE, ONT.—The new high carbon tool steel plant of the International Tool Steel Co., is practically completed and it is expected that operations will start this month. The Standard Ideal Co. have also planned large additions to their plant.

PRINCE RUPERT, B.C.—The Board of Trade are endeavoring to persuade the Granby Co. to establish a smelter here.

TORONTO, ONT.—The new factory of the Gilbert Mfg. Co. is now completed. The company will manufacture stamped copper, nickel, brass and metal goods of every description, using the very latest machinery and dies.

FORT WILLIAM, ONT.—Defective construction caused a fire that did $100 damage to the brass foundry of the Lumby-Stenhouse Co., recently.

PORT ARTHUR, ONT.—It is reported that Sir Donald Mann will come here at an early date with a view to establishing a foundry.

GUELPH, ONT.—Tolton Bros. are making a shipment of harvesters' implements to Australia. The machine shop has been quite busy of late keeping up with the orders. They have the contract for the brackets for the hydro-electric street lights.

OTTAWA, ONT.—The Kingston Shipbuilding Co. has been awarded the contract for the building of the new Government steamer, Dollard. The boat will be used in connection with the lighthouse and buoy service in the Montreal district. The contract price is around $160,000.

BRANTFORD, ONT.—The Buffalo Brake Beam Co. is establishing a plant here and will manufacture brake beams for passenger and freight cars.

TORONTO, ONT.—The Massey-Harris Co. are building an additional factory at their works here.

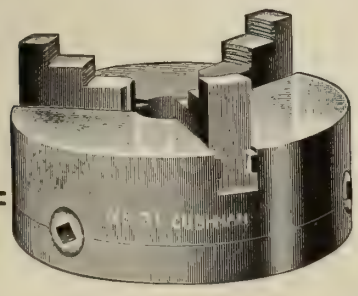
VANCOUVER, B.C.—According to information on the authority of A. P. Gillies, the British Columbia Steel Co., a $10,000,000 corporation, will establish steel rail plants at Port Mann, the Canadian Northern's Pacific terminus, and at Tacoma. The company has acquired an interest in the townsite at Port Mann, and has agreed to erect at least one thousand dwellings to cost not less than $2,000 each.

Arrangements have been completed with the American Car and Foundry Co. to establish a plant at Port Mann with an initial pay-roll of 2,000 men. The plant will turn out steel freight, passenger and sleeping cars, using the available ores at hand. The Pittsburg Plate Glass Company also will establish a plant there, having found sicilia of the best quality in the adjacent district. The furnaces of the steel mills is to be utilized in furnishing fuel for the glass plant.

LONDON, ONT.—The George White Sons Co. is planning extensions of its trade in Western Canada and will, shortly, establish several branches in addition to those now existing at Brandon and Saskatoon.

MONTREAL, QUE.—Fire did approximately $75.000 damage to the Allis-Chalmers-Bullock factory near Lachine, recently. The fire did little damage to the building, which is iron and glass mainly. But everything it contained, including the traveling crane, and all the testing machinery was destroyed, and this being the finishing department for most of the machinery turned out, will greatly hinder some of the other shops. Temporary quarters have been fitted up to keep the work going.

GUELPH, ONT.—The Page-Hersey Pipe Mills here were damaged by fire to the extent of $5,000. The cutting room suffered considerably.



OTTAWA, ONT.—The inauguration of a big shipbuilding enterprise on the Pacific Coast to take a share in the building of Canada's new naval vessels is presaged by the passing of an Order-in-Council granting a subsidy for a dry-dock and ship repair plant of the first-class to the Esquimalt Graving Dock and Shipbuilding Co. According to the estimate of the engineers of the Department of Public Works on the plans submitted, the total cost of the dry-dock with repair machinery, building, etc., will be $2,637,800. The dock will be 900 feet long, 41 feet deep, and 128 feet wide and capable of accommodating the largest vessels afloat. The promoters are Messrs. Bullen, the well-known shipbuilders of the Pacific Coast, who have associated with Denny Bros., of Dunbarton, Scotland, one of

"CUSHMAN" CHUCKS

Our 1911 Catalogue of valuable information regarding

"CUSHMAN CHUCKS"

is now ready. Better write for it. It's free on request.

The Cushman Chuck Co.
Hartford, Conn., U.S.A.
Established 1862

the largest shipbuilding firms in the United Kingdom.

MONTREAL, QUE.—Fire did $20,000 damage to the city workshops recently.

MONTREAL, QUE.—The city is calling for tenders for the filtration plant. Contract No. 1 includes the furnishing and installing of pumping machinery, rotary blower and cranes.

HALIFAX, N.S.—Anticipating the construction of the new Canadian navy, the Nova Scotia Steel and Coal Co., are about to install machinery and adopt a process of manufacturing far in advance of anything yet attempted in Canada which will enable them to manufacture all classes and kinds of the heaviest steel forgings. A new forge house equipped with massive hydraulic forging presses is to be built at New Glasgow. Some idea of the size of the new machinery may be gained from the fact that single pieces of it weigh 80,000 pounds, and the effective power of at least two of the presses will be in the vicinity of 100,000 pounds pressure.

WINNIPEG, MAN. — Thirteen wooden bridges will be replaced on the C.P.R. between Vancouver and North Bend, with steel and concrete structures. A total of thirty new bridges will be put up along the same stretch of line.

OTTAWA, ONT.—A large tool manufacturing company will locate here if satisfactory terms are secured from the city,

GALT, ONT.—The Down Draft Furnace Co. are erecting a large addition for their nickel-plating department.

WINNIPEG, MAN.—The C.P.R. has awarded several contracts for improvements in the Weston shops.

Carter, Halls and Aldinger have been awarded the contract for the erection of a large upholstering shop. This building will be 98 feet long and 74 feet wide and 16 high.

The J. McDiarmid Co. will build a new boiler shop, the dimensions of which will be 286x118 feet feet. The building will be constructed of brick.

In addition to these the Jackson & Golding Co., of St Boniface, have been awarded the contract to put in concrete foundations for a new transfer table.

VANCOUVER, B.C.—The firm of McDougall, Jenkins Engineers Ltd. of North Vancouver, are building a $150,000 extension to their plant. This price includes the figure at which the stock machinery and other assets of the Albion Iron Works were acquired.

MONTREAL, QUE.—Work has been started at the Angus shops on an order for 2,000 steel box cars. This is the second part of a $3,500,000 order placed last fall.

WINNIPEG, MAN.—The $1,500,000 contract at Transcona for the completion of coach shops and buildings has been awarded to Haney, Quinlan & Robertson, which firm has just finished the erection of the shops at Transcona for the commission and the Grand Trunk Pacific.

MONTREAL, QUE.—The C.P.R. Angus shops recently issued ten new switching engines of standard size, to be distributed along the company's lines.

Municipal

GALT, ONT.—The by-law authorizing expenditure of $25,000 on the hydro-electric system was carried.

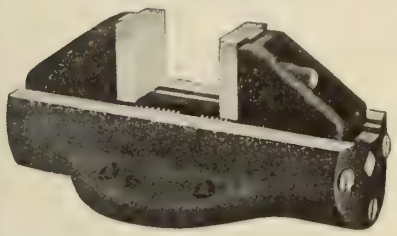
TRENTON, ONT.—A by-law will be submitted to raise $700 by way of debentures to purchase site for a baby carriage factory.

LINDSAY, ONT.—Lindsay is to be asked to loan $50,000 in the matter of the re-organization of the Sylvester Manufacturing Co.

GUELPH, ONT.—The Independent Tire Co. will locate here.

CHATHAM, ONT.—An $80,000 pork and beef packing plant is to be erected here by O'Keefe & Drew. It is being built for the purpose of taking care of 75 per cent. of the hogs and cattle slaughtered in the western peninsula.

MELVILLE, SASK.—The following by-laws were passed here: Electric light, $23,000; sewers, $5,000, and waterworks, $63,000.



VANCOUVER, B.C.—By-laws aggregating $1,370,000 will be voted on as follows: Sewers, $750,000; Clark Drive, $35,000; street improvements, $60,000; water, $115,000; street improvements, $75,000; water, $75,000; main along Seymour Creek, $100,000; grading, rocking and planking, $100,000; isolation hospital, $50,000; jail, etc., $30,000.

ESTEVAN, SASK.—Two by-laws will be submitted to the ratepayers for approval, $5,000 for waterworks extensions, and $18,000 for cement sidewalks.

PORT ARTHUR, ONT.—Three by-laws will be voted on as follows: Street railway purposes, $25,000; floating debt, $15,000, and $100,000 for the extension of the intake pipe and an additional standpipe.

CRANBROOK, B.C.—A by-law to install a sewer system in Cranbrook carried.

MONTREAL, QUE.—The city contemplates on expenditure of $1,293,883 on water mains and sewers.

NORTH BAY, ONT.—Two by-laws will be voted on, $45,000 for sewerage purposes, and $100,000 for waterworks.

WINDSOR, ONT.—The city contemplates a by-law to expend $50,000 for an intake and construction in connection with new water supply.

SOUTHAMPTON, ONT.—The by-law to expend $7,500 to extend the waterworks system here was carried.

SCOTT, SASK.—By-laws authorizing the installation of waterworks, sewerage and electric light have been carried by a large majority.

WINDSOR, ONT.—A by-law will shortly be submitted to provide $50,000 for the extension of water mains.

SUDBURY, ONT.—By-laws are under consideration aggregating $100,000 to $150,000 for municipal improvements, including water mains, trunk sewerage mains, lake sewerage disposal, auxiliary fire pumping plant, new fire hall and apparatus, fire alarm system and permanent roads.

OTTAWA, ONT. — By-laws aggregating $330,000 will shortly be submitted, $150,000 to complete the waterworks aqueduct, $60,000 for a booster system, $45,000 water mains, and $80,000 for the high-level bridge over Bank Street.

RENFREW, ONT.—The ratepayers recently passed a by-law granting $3,000 for sewerage.

ESTEVAN, SASK.—Two by-laws will be submitted to the ratepayers for approval, $5,000 for waterworks extensions, and $18,000 for cement sidewalks.

BERLIN, ONT.—Fourteen thousand dollars profit was shown at the end of last year from the operation of the Berlin waterworks department. For years past surpluses have been shown by this department, but the money has been spent in extensive additions to the system.

VICTORIA, B.C.—Victoria ratepayers have carried three of the five money by-laws submitted. Each received a three-fifths majority. Those carried were a vote of $150,000 additional school expenses asked for by the school board and declined by the city council; $300,000 for extending the sewer system, and $30,000 for an alteration to the market building for other civic purposes.

WILKIE, SASK.—The town council have engaged a municipal engineer and it is likely that Wilkie before the fall will have a complete system of waterworks.

MOOSE JAW, SASK. In the electric light department there will be expenditures this year of $50,000 for improvements and extensions. Of this amount $15,000 is to be spent on ornamental street lights. A sum of $35,000 is to be spent on electric light extension in addition to the ornamental improvement.

PENTICTON, B.C.—Tenders will be received for the following debentures; $150,000 40 years 5 per cent. domestic water loan; $71,000 40 years 5 per cent. electric light.

STETTLER, ALTA.—Tenders will be received for $17,000 20-year 5½ per cent. electric light; $6,000 10-year 5½ per cent. local improvements; $2,000 20-year 5½ per cent. chemical engine and hose, and $3,500 20-year 5½ per cent. municipal buildings.

COBALT, ONT. Tenders will be received for $43,500 waterworks and sewerage, debentures, 6%, 10-year sinking fund bonds, issued under by-law No. 143, and confirmed by Chap. 87, Statutes of Ontario, 1911.

Electrical.

MONTREAL, QUE.—The Canadian Light & Power Co. have completed arrangements for using the power house and plant of the Central Light, Heat & Power Co., which they acquired some time ago. The deal was put through four months ago, the price paid being half a million dollars. At the time, however, no details were available regarding the plans of the Canadian Co. The present capacity of the power house, 2,000 horse-power, will suffice for present needs, but it is the intention of the Canadian Light & Power Co. to extend the business as much as possible. With this end in view the present steam-driven dynamos will be removed as soon as possible and the power brought from the Beauharnois power houses of the company.

LINDSAY, ONT. Lindsay will submit a by-law to raise $230,000 for the purpose of purchasing the plant of the Light, Heat and Power Co.

GUELPH, ONT.—Niagara power is now being used exclusively by the Light and Heat Commission in supplying light and power to its patrons.

MIDDLETON, N.S.—This town is contemplating a by-law to borrow $15,000 for the purpose of purchasing and installing an electric light plant.

PRINCE ALBERT, SASK.—The city is calling for tenders for the construction of a dam and headworks and canal and power station foundations which are portions of the proposed Hydro-Electric Power Development, on the North Saskatchewan River, at La Colle Falls.

LETHBRIDGE, ALTA.—The Carmanga town council is taking steps to install a municipally-owned waterworks and electric light system. They have already secured an option on the electric light plant owned by C. W. Carman, which lights the town at present.

ST. JOHN, QUE.—Fire destroyed half a dozen small residences and then spread to the municipal electric plant, which was also wiped out. The total loss is placed at $75,000, with insurance of about half that amount.

HAMILTON, ONT.—Machinery will be installed at the Cataract Power plant to raise the capacity from 38,000 to 60,000 h.p.

NELSON, B.C.—Intimation is given of a new electric power proposition of great magnitude in papers made out by A. L. McCulloch, mining engineer, of Nelson, giving notice that on June 16 he will apply to W. F. Teetzel, water commissioner for the Nelson water district, for a license to use 6,300 cubic feet of water per second for power purposes, from the Kootenay river.

WINNIPEG, MAN.—The first actual business addressed to the new civic power manager, J. B. Rossman, was received by Mr. Rossman at the city hall recently. This was contained in a letter from the local industrial bureau asking for a definite price on 100 24-hour horse-power. This power is wanted by a new industry, which it is proposed to establish in the city. The buildings for this plant will cost approximately $125,000.

EDMONTON, ALTA.—The city council are preparing to spend a quarter of a million dollars for the purchase of machinery for the power plant.

MONTREAL, QUE.—Plans for the construction of an immense dam at the foot of the Coteau Rapids, in the St. Lawrence, which, if completed, would mean the development of an equally large amount of water power, are now under consideration by a commission of Government engineers. The Canadian Light & Power Company is promoting the scheme.

RENFREW, ONT.—$125,000 will be spent for new electrical equipment.

SANDWICH, ONT.—R. Stuart will erect a power house here.

KNOWLTON, QUE.—A municipal power plant will be started here.

ST. JOHN, N.B.—The Eel River Light, Heat & Power Co. will build a large power plant near here.

MAGOG, QUE.—A new power station will be built here.

PRINCE RUPERT, B.C.—The Prince Rupert Power Co. will build a lighting plant here, to cost $3,000,000.

TAVISTOCK, ONT.—$30,000 will be spent on electrically-operated pumps for waterworks.

NORTH BAY, ONT.—North Bay will buy $100,000 worth of electrically-operated waterworks machinery.

MIDLAND, ONT.—The electors have declared in favor of Hydro-Electric power. The by-law provides for the expenditure of $13,000, and the service will include both power and light. It is only necessary to string wires to complete the equipment, and this, it is expected, will be done by June 1.

VANCOUVER, B.C.—Notice has been given of the application of the Howe Sound Power Co., for water rights for power purposes on Furry Creek, a stream which flows into Howe Sound at a point three miles south of Britannia Beach. The Howe Sound Power Co. is noted as a concern with a capital of $100,000. The promoters decline to give any particulars concerning the development of the Furry Creek power, but the details noted in their application show that the plans in mind are extensive.

General Manufacturing

MONTREAL, QUE.—J. C. Wilson & Co., paper manufacturers, will build a large fireproof building here this summer.

REVELSTOKE, B. C. Chas. A. Barnum, general manager of the Diamond Mills Co., and the Dominion Securities Co., is handling a big project, which involves the building of pulp and paper mills in the interior, the erection of a large sawmill at the Big Eddy, the construction of a large power dam on the Columbia river, the syndicating of about seven hundred thousand miles of pulpwood and timber and the initial investment of several millions of dollars, while as an outcome of all this increased enterprise a large army of men will be employed.

MANUFACTURERS OF
THE "SWIFT" MARINE ENGINE

NEW GLASGOW, N.S. - The Pickering Wheel Co. is preparing to establish a factory here. The new concern will cater particularly to the heavy wheel trade, such as express and wagons and heavy cartage.

BELLEVILLE, ONT. The Allard Platinum & Gold Refining Co., of Rochester, N.Y., propose establishing a plant here.

CHATHAM, ONT.—Tripplehorn Bros., of Findlay, Ohio, have decided to open a cement and tile manufacturing industry in this city, to be known as the Chatham Cement Tile & Block Co. They will erect two buildings 60 by 70 feet and 40 by 75 feet

SHERBROOKE, QUE. A new industry has started in Sherbrooke, known as the Railway Asbestos Packing Co. They expect to erect their own factory later on.

LINDSAY, ONT.—Horn Bros. are building an addition to their factory here.

SARNIA, ONT.—The Lott Lawn Fence Co. have opened a new business here to manufacture ornamental lawn fence and patent gates.

PORTAGE LA PRAIRIE, MAN.—The Great West Bedding Co. are locating here.

PORT ARTHUR, ONT.—R. McArthur, of Deseronto, is establishing a match factory here.

MULGRAVE, N.S.—G. T. McNutt is establishing a woodworking factory here.

SARNIA, ONT.—The Port Huron Creamery Co. have opened up an up-to-date plant here.

CALGARY, ALTA.—Either next fall or early next spring, work will be started on a million-dollar packing plant in Calgary. It is to be built by the large packing concern known as Morris & Co., of Chicago, of which the Dominion Meat Co., of Calgary, is a branch.

BROCKVILLE, ONT.—The National Manufacturing Co. will locate here.

SARNIA, ONT.—The Canadian Woodworkers are building a new factory here. It will be of re-inforced concrete.

GUELPH, ONT. The city council has granted fixed assessments of $1,000, except for school taxes and local improvements, to four firms. They are the Colonial White Wear Co., the Canada Textile Weaving Co., the Emery Manufacturing Co., and the Taylor Stratton Dairy Co. The first-named company is to erect a new building on another site and increase the staff by 150 hands.

KENORA, ONT.—A new industry, known as the Gullberg-Ekberg Co., recently started operations for the manufacture and sale of tar, creosote, turpentine, charcoal, etc., at the Winnipeg river crossing of the Grand Trunk Pacific. The plant is in close proximity to the Winnipeg river on the new townsite, and the location warrants a splendid supply of raw material very easily assembled by the river.

BERLIN, ONT.—The following factories will make extensions this year: Kaufman Rubber Co., L. McBrine & Co., D. Hibner & Co., Kaufman Planing Mill, Canadian Pyrofugont Co., Cloisonne Art Glass Co., Lang Tanning Co., C. H. Doerr & Co., Interior Hardwood Co. and Walker Bin and Fixture Company.

GODERICH, ONT.—An English syndicate purposes establishing a big works here to manufacture salt by a new process.

TORONTO, ONT.—The Royal Shoe Co. have purchased a factory and will locate here.

OWEN SOUND, ONT.—Two by-laws were carried here recently. The knitting factory by-law passed gives Lake and Ward, promoters, a loan of $15,000 for twenty years at 4½ per cent. The second one was a by-law to loan $25,000 at 4½ per cent. for twenty years to parties identified with the Adams Furniture Co., of Toronto. The new factory will manufacture high-class furniture and upholstered goods.

MONCTON, N.B.—The A. J. Burton Saw Co., Vancouver, are asking the Board of Trade what the city will give them if they move a part of their saw plant to Moncton. They would employ about 50 men.

ST. CATHARINES, ONT.The old McCleary & McLean lumber yard will be fitted up and a tissue paper factory take its place. New machinery will be installed and water power used.

Building Notes

AURORA, ONT. The by-law to loan the Positive Clutch & Pulley Works $10,000 was carried.

VANCOUVER, B.C.—The C. P. R. intend erecting a ten storey office building here, to cost $200,000.

EDMONTON, ALTA. R. F. Klein has organized a company to erect an $85,000 hotel here this summer.

WINNIPEG, MAN. D. McDonald, western manager of the Confederation Life, has announced that the institution will proceed with the erection of a ten-storey office building, to cost $1,500,000.

EDMONTON, ALTA.—J. E. Wize, architect, has prepared plans for a six-storey building for Dr. McLean, to cost $130,000.

SASKATOON, SASK.—J. F. Cairns will erect a mammoth departmental store here.

REGINA, SASK.—The plans for the new union depot are completed and are in Regina. The building will cost in the neighborhood of $200,000.

TORONTO, ONT.—The following permits have been granted: M. Rawlinson, six-storey warehouse, $30,000; Western Baptist church, church and Sunday school, $40,000; the Toronto Carpet Co., five-storey factory, $90,000.

VANCOUVER, B.C.—C. Fee has taken a permit to erect a $100,000 block.

TORONTO, ONT.—It has been decided to add three more storeys to the Home Life building, at the corner of Victoria and Adelaide Streets. This will make a nine-storey building. The cost of the work is expected to be about $100,000.

TORONTO, ONT.—The premises occupied by the store of John Catto & Sons, have been purchased by a Montreal syndicate represented by J. Lewis Thomas. The purchasers will erect on this site within three years, a splendid office building about fifteen storeys high.

VANCOUVER, B.C.—Plans have been prepared for a six-storey building to be erected by the Otis-Fensom Elevator Co. Construction will be undertaken this spring and it is announced that the building will cost approximately $100,000. The company is also considering the erection of a warehouse on Railroad avenue.

TORONTO, ONT.—The Dominion Government has decided to expend $500,000 in Toronto in a central building that is to accommodate all the offices at present scattered all over the city.

VANCOUVER, B.C.—A permit was granted the B.C. Sugar Refinery for a filter-house to cost $75,000, to be constructed with steel frame and concrete floors. The architect is Kennedy Bryan.

TORONTO, ONT.—According to Transportation Manager W. G. Brownlee, the G.T.R. will spend several millions in improvements during the present season. One of the schedule undertakings is the construction of a roundhouse at Midland. It is unlikely, however, that any new extensions will be made to the Toronto portion of the system during the coming summer.

EDMONTON, ALTA.—Sherman and Lougheed, of Calgary, will erect a $150,000 theatre here.

CALGARY, ALTA.—Plans and specifications for the C.P.R. hotel call for a 13-storey structure, although but 8 storeys will be built this year. When completed, the cost will be $1,500,000.

TORONTO, ONT.—An initial expenditure of five million dollars, and an ultimate expenditure of between thirty and forty millions, is to go towards the construction of the Canadian Northern terminals in Montreal and Toronto. Thirty million dollars is to be spent in Montreal terminals, in time, and some five or six millions in Toronto.

Planning Mills

AMHERST, N.S.—The mill owned by Rhodes-Curry Co. at Little Forks was totally destroyed recently. The mill was equipped with modern machinery and this spring a large sum of money was used in fitting it out in first-class shape for the summer operations. The mill was 30 feet by 110 feet, and under the same roof were the planing mill, 90 feet by 30 feet, the lath room, 25 feet by 20 feet, and also the boiler room, 40 feet by 20 feet. All these buildings have been wiped out. The loss will be $25,000.

TORONTO, ONT.—Fire did $1,000 damage to the planing mill of J. C. Gilchrist at the corner of Ernest Ave. and Perth. The loss is fully insured.

OTTAWA, ONT.—W. F. MacGlasken, general manager for the Beaver Manufacturing Co., of Buffalo, was in the city to confer with the local officials of the company with a view of building a large factory on Bayswater Ave. The new plant will turn out a quarter of a million square feet daily.

SIMCOE, ONT.—Fire destroyed the planing mill of D. G. McKnight, here, recently. The loss is fully insured.

ST. JOHN, N.B.—A fire of unknown origin caused the complete destruction of J. A. Gregory's saw mill at Lepreaux. The mill is a complete loss, the machinery is probably totally destroyed and 300,000 laths went up in smoke.

HATLEY, QUE.—Fire did several thousands of dollars damage to the saw mill in connection with the Hatley Dairy, Light and Power Co.

WOODSTOCK, ONT.—T. D. Broom & Son have just completed a new factory to supply building materials of all kinds.

HALIBURTON, ONT.—Austin's saw and shingle mill was completely destroyed by fire recently. Loss will be $4,000.

PARRY SOUND, ONT.—The box factory of the Parry Sound Lumber Co. was completely destroyed some time ago.

HALLVILLE, ONT.—The saw mill and cheese box factory of Messrs. Shaw & Earl was damaged by fire recently.

ST. JOHN, N.B.—The new planing mill of Atkin Bros at Fairville, is rapidly nearing completion.

ANNAPOLIS ROYAL, N.S.—The saw mill at Young's Lake, owned by Sylvester Bent, of Belleisle, was burned out recently.

WATERBOROUGH, Q.C., N.B.—M. Vicars steam saw and grist mill was destroyed by fire recently. It is being rebuilt.

NEEPAWA, MAN.—1,000 feet will be added to the floor space of the sash and door plant and planing mill of the Fusee, McFeetors Co.

KINBURN, ONT.—Fire did $350 damage to the saw mill of H. Lowry & Sons, of Marathon.

CHATSWORTH, ONT.—The sawmill of Alex. Brown, on the 2nd line of Derby, was completely destroyed by fire. The machinery is a total loss.

PORT ARTHUR, ONT.—The city has concluded an agreement with J. L. McRae to establish a factory to cost $60.000, to manufacture interior finishings, the city guaranteeing the bonds for half that amount on first mortgage.

MEDICINE HAT, ALTA.—J. H. Preston will spend $50,000 on a planing mill business here.

VANCOUVER, B.C.—Davidson & Labsik, manufacturers of sashes and doors, have assigned.

VANCOUVER, B.C.—The saw mill of W. H. Day, suffered loss by fire some time ago.

A METAL MERGER.

By the amalgamation of the King Radiator Co., Montreal, the Expanded Metal Fire Roofing Co., Toronto, and a number of other important plants, another merger in the basic industries has been effected in Toronto. The combination involves a five million dollar capitalization and in addition to the existing plants in Toronto and Montreal, it is understood that contracts have been awarded for the erection of a large factory in St. Catharines which will supplement the company's output in the larger cities. It is also understood that options on two important industries of a similar character in the Maritime Provinces will be closed and the activities of the new combination will then extend over three-quarters of the Dominion. Toronto banks underwrote $750,000 of the present bond issue of $1,500,000.

New Companies

MONTREAL, QUE.—The Dominion Architectural Ironworks, Ltd., capital $100,000, have been incorporated to manufacture and deal in metal products, and carry on the business of iron-founders, steel-makers steel converters, etc., etc. G. Humphreys, manufacturer; J. R. Estey, engineer; R. Taschereau, T. Rinfret and R. Genest, advocates, all of this city.

LONDON, ONT.—The W. J. Reid & Son, Automobiles, Ltd., capital $100,000, have been incorporated to manufacture, repair and deal in automobiles, motor cars, etc. W. J. Reid, merchant, F. A. Reid, commercial traveler, R. D. Aldrich, sales manager, C. G. Lewis, bookkeeper, all of this city; and G. E. King, capitalist, of Detroit.

MONTREAL, QUE.—The Grand Metis Power Co., capital $100,000, have been incorporated to carry on the business of a light, heat and power company, and acquire all necessary works, engines, machinery, generators, etc., etc. W. J. Shaughnessy, advocate; T. S. Owens, student; A. E. Woodworth, accountant; A. B. Wright and A. Charters, clerks; all of Montreal.

TORONTO, ONT.—The Masco Co., capital stock $100,000, have been incorporated to carry on the business of electricians, mechanical engineers, manufacturers and dealers in electrical machinery and supplies, etc. E. G. McMillan, law student; J. F. McGregor and W. H. Walter, accountants; H. Riley, law clerk and A. Bicknell, solicitor; all of this place.

VICKERS FLOAT FIVE MILLION FOR CANADA COMPANY.

LONDON, ENG.—Messrs. Vickers, Son and Maxim, shipbuilders and engineers, have applied for powers for the incorporation of their Canadian Company to build and operate a floating dry-dock at Montreal with naval works and factory for the construction of steel railway tires and other industrial operations on the site granted for the purpose under the agreement between the company and the Montreal Harbor Commissioners and the Government of Canada.

The capital of the new company will be $5,000,000, and with the Government subsidy of the first class under the Act authorizing the granting of subsidies for the erection of dry docks, it is expected that the financing will an easy matter and the works will be pushed on so that the floating dock, which will be built at Barrow and will complete the naval establishment well advanced in 1912.

Catalogues.

BOLT MACHINERY—Webster & Perks Tool Co., Springfield, Ohio, have issued a catalogue on coated paper, 30 pages, 9x6 ins., describing bolt pointing, threading, and special tapping machines. All the machines referred to are well illustrated.

Editor Wanted

Graduate of McGill or S.P.S. in Mechanical Engineering to do editorial work on "The Power House" and "Canadian Machinery." State age, particulars regarding practical experience, etc.

MacLean Pub. Co., Ltd;
Eastern Townships Bank Bldg.
MONTREAL

SMALL MILLING MACHINES—The Chicago Machine Tool Co., 127 North Canal St., Chicago, Ill., have just published a catalogue of their Chicago small milling machines. This catalogue deviates considerably from the general run of catalogues, inasmuch as the net prices of both the machines and their attachments, are given. These millers are illustrated in their various sizes and styles from the stripped machine to the complete machine, in each case the equipment and net price of the machine is stated.

ELECTRIC FURNACES—Verdon, Cutts & Hoult, Town Hall Chambers, 87 Fargate, Sheffield, have issued a booklet on electrical manufacture of steel in the Electro-Bessemer furnace. Electric welding and annealing furnaces are also dealt with in the catalogue.

SOLID ADJUSTABLE DIE HEADS — A pamphlet from the Landis Machine Co., Waynesboro, Pa., describes the solid adjustable die head. An illustrated description appeared in a recent issue of Canadian Machinery.

CRANES—The Whiting Foundry Equipment Co., Harvey, Ill., represented in Canada by the Dominion Foundry Supply Co., Montreal and Toronto, have issued Catalogue No. 77, which shows illustrations of a number of recent installations of cranes and other foundry equipment.

MACHINERY—John B. Hall & Sons, Brantford, Ont., have issued a folder containing leaflets which describe a number of machines manufactured by them, including bench grinders, pedestal grinders, lawn mower and skate grinders, hand winches, cold saws, etc.

BALL BEARINGS — A description of "Swivel Double-row Ball Bearings for Shafting," with illustrations, has been received from the Unbreakable Pulley & Mill Gearing Co., Manchester and London, Eng. The Canadian agents are Vandeleur & Nichols, Dineen Building, Toronto.

Book Review.

MACHINE SHOP MECHANICS—By Fred H. Colvin, A.S.M.E., F.I.; 177 pages, 4½x7 ins., illustrated; published by the McGraw-Hill Book Co., 239 West 39th St., New York. Price $1 net.

This book has been given the title of Machine Shop Mechanics, or the "Why of Things in the Machine Shop," as it explains the "why" of many happenings in everyday work, such as friction and the various forces which come into play when any work is performed. There are twenty chapters dealing with levers, the screw and wedge, inclined planers, gravity, friction, heat, inertia, belts and pulleys, block and tackle, gearing, centrifugal force, hydraulics, steam pressure, force of a blow, strength of materials, shafting, action and reaction, beams, measuring moments, and force diagrams. The book will be found of great value to the man who wishes to know the "why" of things.

PROTECT YOUR EMPLOYEES

By Using

"D.L." Standard Metal LOCKERS

Do not allow your employees to run the risk of contagion. You are apt to lose an experienced man's valuable time while he is on the sick list.

Install the "D.L." Steel Lockers

They are **sanitary** and protect your workmen from contagion.

They are **absolutely fireproof, prevent theft, economize space, save contents, reduce your insurance rates and promote order and system.**

The "D.L." Steel Lockers are unequalled for **strength, durability** and **finish,** and are most economical to install.

Write to-day for catalog and further information

BROWNING

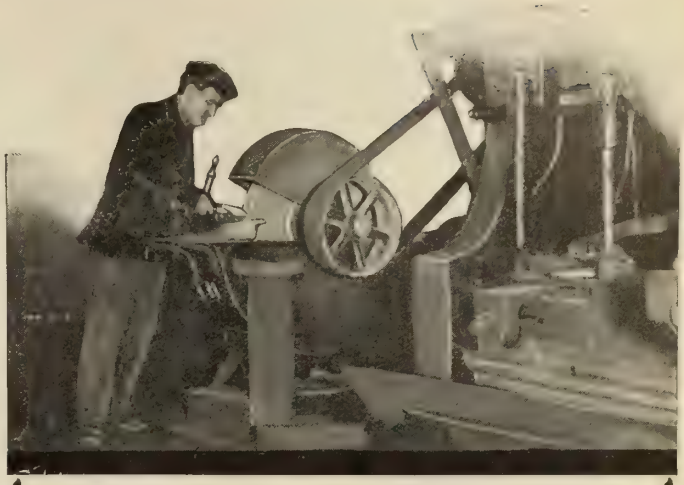
The Browning Locomotive Cranes are

Reliable, Durable, Economical and Accessible.

In the end a Browning Crane will cost you less than ordinary labor and will have accomplished more.

They are built for the heaviest lifting, such as logging, contractors' work, etc., and perform their functions with the greatest of ease.

INSTALL A BROWNING CRANE



and it will bring you surprising results.

Remember it will save you money. Write for illustrated catalog and full information.

The Browning Engineering Co.

Cleveland, - Ohio

CRANES

A Carborundum Wheel Grinding Steel Drills Three Months Night and Day Was Still Cutting Clean and Fast and the Wheel Loss Wasn't Noticeable

This remarkable record was made in a steel car-making plant. The wheel was a regular 24 inch Carborundum wheel and it kept seven multiple drill presses going night and day for three months—showed but little wear and cut fast, clean and cool every minute—it is no wonder that the operators said it was the best wheel they had ever used.

In your own shop you may have just this or any other grinding condition to meet. There is a Carborundum or Aloxite wheel to meet it at a saving of time and money---Let us help you get the right wheel in the right place.

A GOLD MINE

SAVE YOUR IRON

SLY'S PATENT IRON CINDER MILL
Patented, No. 514097. Patented, No. 841728.

may be at your disposal on your very premises. Look out of your side window or back door and see if you have not an accumulation of cupola dump, and other foundry refuse, which is a total loss to you in its present state. Why not add to your profits and install one of the Sly Patent Cinder Mills to reclaim this iron and be astonished at your former loss and pocket the rich re. turns from your newly-discovered mine-

Sly's Patent Iron Cinder Mill will save 95% of the iron contained in your cupola dump and gangway scrapings and 75% of the coke. Iron is valuable, then why throw it in the dump? Iron recovered by this Mill is better than machinery scrap. Study economy in a foundry and your profits will increase accordingly. Mill will pay for itself three or four times every year, and we have records of Mill paying for itself twelve times a year. Let us know amount of your daily melt and we will quote. *Write for Cinder Mill Catalogue F.*

We also manufacture Cleaning Mills, Dust Arresters, Sand Blast and Foundry Equipment.

The Making of Hollow Castings

The recent introduction of King Kore Kompound has now rendered this, once somewhat difficult, part of Foundry practice comparatively easy.

It has, also, reduced the core expense by more than one-half.

This compound is a black, dry powder, and is used as flour is used, but with one-half the quantity is produced greater and better results.

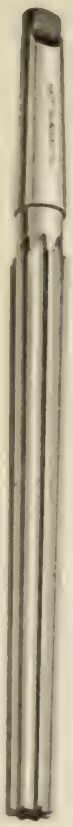
Its use avoids the danger of swelling or "blowing." The core easily comes out of the casting, and when old cores are ground up, in the rattler, or otherwise, the sand so made is used over again.

The core compound it contains, again becomes a binder under heat of the core oven, as it melts, and so it is used over and over again.

This is Foundry Economy; Flour, Rosin, etc., are now luxuries.

A barrel of King Kore Kompound will be sent "subject to approval" to any inquiring mind.

That is the **Stevens' System** of trying before buying.



I have copies of proportions of compound to sand used and methods followed in core rooms of Foundries in thirteen different States. This information, with other printed matter relative to the subject, will be mailed on request.

I maintain a direct branch at 137 Jarvis St., Mr. J. M. Mayers, Manager, Toronto, Ont., where is stocked a supply of **Foundry Facings, Foundry Supplies, Buffing Compositions**, of my own manufacture.

The stamp of quality pervades them all.

FREDERIC B. STEVENS

OILDAG

(Registered Trade Mark)

Deflocculated Acheson-Graphite, Dag and Oil.

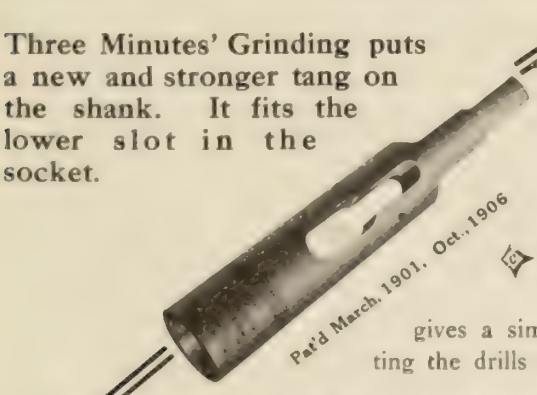
Graphite does not dissolve in any liquid or break under pressure, and these qualities, added to the unctious softness and purity, together with its non-coalescing nature, make Acheson-graphite ideal for lubrication purposes.

The process of deflocculation takes Acheson-graphite powder so fine that 99% of it will go through a sieve having 40,000 meshes per square inch, and sub-divides each grain of this finest powder into many still smaller particles—so small that they cannot be seen through a strong microscope.

Oildag is this deflocculated Acheson-graphite suspended in oil, where it neither floats or sinks, but is evenly distributed throughout. Oildag will flow anywhere the oil alone will go.

Mr. Robert A. Ross, E.E., of Ross & Holgate, Consulting and Supervising Engineers, Montreal, writes:

"As my firm are constructing and operating steam plants, we have wished to use a mixture of graphite and oil for cylinder lubrication, but have been prevented by the fact that the graphite settled out of the mixture. **This difficulty you have overcome,** and we are now assured of the best lubrication in the world, especially in superheated steam practice."



Write for Oildag Booklet 77D.

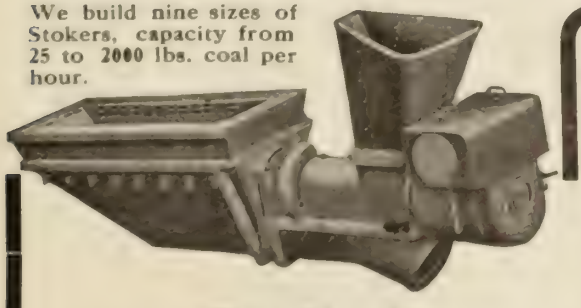
We are General Agents for Gredag, made by the International Acheson-Graphite Company.

ACHESON OILDAG COMPANY

Factory at Sarnia, Canada **Port Huron, Michigan**

Three Minutes' Grinding puts a new and stronger tang on the shank. It fits the lower slot in the socket.

What Do Your Twisted-Off Tangs Cost?



Keep account for a time of the new drills used to replace those thrown into the scrap heap because of twisted-off tangs, and you will see. These scrapped drills are all right in every other respect.

The "PERFECT" Double-Tang Socket

gives a simple, effective, and inexpensive means of eliminating this cost and putting the drills back in money-earning shape. **Write for Folder A.**

The Cleveland Twist Drill Co. CLEVELAND Chicago New York

We build nine sizes of Stokers, capacity from 25 to 2000 lbs. coal per hour.

Write Now!

Our Furnaces Heat Steel with the Cheapest Fuel on Earth—

SOFT, SLACK COAL

They are all fired with "American" Mechanical Stokers, which burn bituminous slack coal automatically and without smoke, and give a clear, steady, soft, non-scaling flame. You get increased production, at about one-third to one-half the operating cost of oil or hard coal. This is a fact. If you burn money to heat steel why not burn less of it, and write us at once?

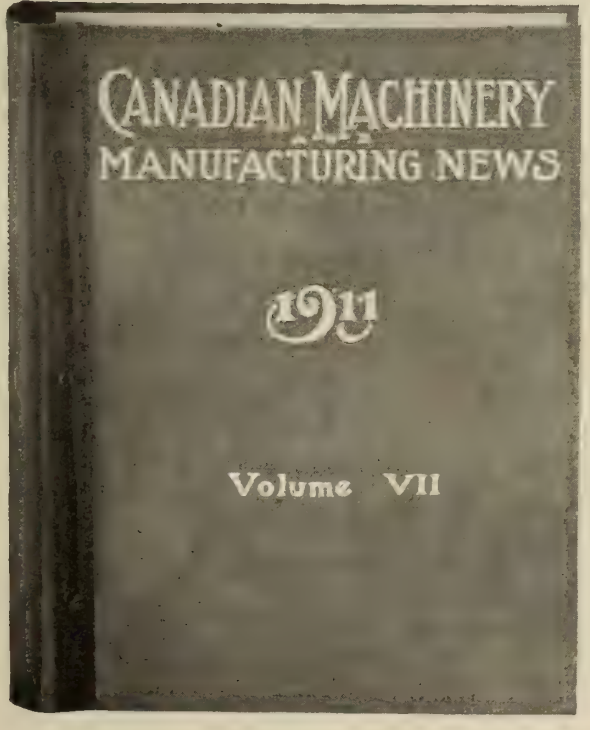
FOX Multiple Spindle Drills



You are not producing your work at the lowest possible cost unless you are using a **Fox Multiple Drill.**

The machine shown drills 6⅝-inch holes in aluminum, cast iron or steel, and spindles can be set to a 9-inch circle.

We also build machines to drill layouts up to 16x 30 inches, rectangular or irregular, and circles 24 inches in diameter, carrying as large as 1¼ inch drills.

WRITE TO-DAY FOR FULL INFORMATION

FOX MACHINE COMPANY
23 N. Front St., Grand Rapids, Mich.

The Technical Papers of To-day

ARE THE

Textbooks of To-morrow

¶ **Therefore,** Be in advance of the times by binding your copies of Canadian Machinery. To help you do this and, in addition, assist you in keeping them clean and easy of access for reference, we will send Canadian Machinery for one year and a "Common Tie" Binder for $1.50, or to present subscribers we will furnish the binder at 50c. each post paid.

¶ At the end of the year a complete alphabetical index will be furnished free.

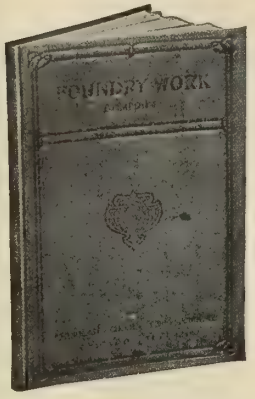
FIRE BRICK *for* Cupolas

¶ The standard Fire Clays by which all other Clays are judged are those of Pennsylvania.

¶ They're the ones from which our Cupola Brick are made.

¶ The cost per thousand means nothing unless you know the results the Brick are giving.

¶ Write us for definite examples of how our material affects your melting costs.



HARBISON-WALKER REFRACTORIES COMPANY,

PITTSBURGH, PENNSYLVANIA

You May Have This Book Without Spending a Cent

if you are a subscriber to "Canadian Foundryman," by sending in to us four new paid-up subscriptions. If you are not a subscriber send in your own, along with the proper number of paid-up subscriptions and the book is yours.

Foundry Work

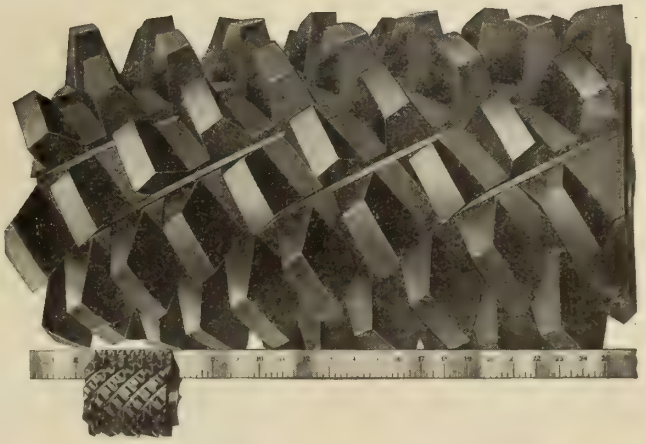
By Wm. C. Stimpson

Head Instructor in Foundry Work and Forging, Department of Science and Technology, Pratt Institute.

160 pp., 150 illus. Cloth binding. A practical guide to modern methods of molding and casting in iron, brass, bronze, steel and other metals, from simple and complex patterns, including many valuable hints on shop management and equipment, useful tables, etc.

Price, $1.00

Given free with four yearly paid-up subscriptions.



The subscription price is fifty cents per year; two years for one dollar.

Canadian Foundryman

143-149 University Avenue, Toronto

We Make Accurate Hobs

WORM GEAR HOBS

SPUR GEAR HOBS

The manufacture of accurate hobs is a difficult task and cannot be accomplished by the aid of special facilities alone. Long experience, together with specially designed machines for cutting and relieving the hobs, are a necessity. So, also, are special machines needed for grinding, but when it comes to the hardening, no rules can be given. Here experience counts, for each hob must be treated differently, according to the size, hole, length, etc. *We have made hobs for more than 20 years.*

¶ Scientifically selected and graded for the work required.

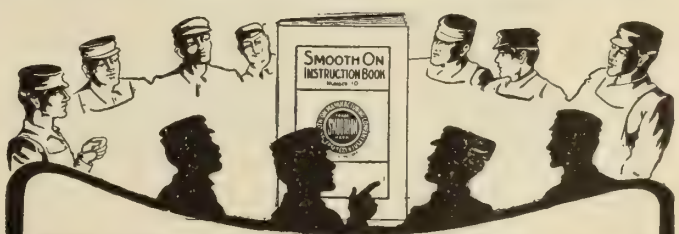
¶ Large Capacity. Prompt Service. Unequalled Quality.

ALBANY SAND & SUPPLY CO.

ALBANY, N.Y.

This Company's Product is used in Stove Foundries in England.

FOR SALE



Slightly used Electrical Apparatus as made by Electrical Construction Company of London, Limited. On hand at Chatham, Ontario. In use about one year. Everything in first class condition. Price less than one-half original cost.

1. D.-C. 110-volt Switchboard, complete with bus bar connections and equipped as follows:
   1—36"x51x1½x3-16" Bevel Blue Vermont Marble Panel.
   1—Angle Iron Framework for above panel, 6' 4½" high.
   1—Type F. D.C. Weston Voltmeter O-130 Voly Scale, No. 61437.
   1—Type F. D.C. Weston Ammeter, O-600 Amp. Scale No. 61263.
   2—Bracket Lights for instruments.
   1—1-T.E. S.P. Circuit Breaker, Type N.X. 600 Amp. 250 Volts, Calibration 450-900 Amp. No. 5584.
   3—200 Amp. 250 Volt D.P.S.T. back connected enclosed fused knife switches. Fuses at bottom.
   1—500 Amp. 250 Volt D.P.S.T. back connected knife switch.
   1—75 Amp. 250 Volt D.P.S.T. back connected knife switch.
   1—Ward-Leonard 15" Rheostat, Type F-112-5, complete with hand wheel and dial for front of panel mounting.
1. 80 K.W. 110 Volt 570 R.P.M D.C. Compound Wound Generator, No. 2176, complete with slide rails and pulley, 24" dia. x 12½" face.
1. 11 K.W. 110 Volt, 925 R.P.M. D.C. Compound Wound Generator, No. 1722, complete with slide rails and pulley 9½" dia. x 5½" face.
1. 24 K.W. 110 Volt, 500 R.P.M. D.C. Shunt Wound Motor, No. 2177, complete with slide rails and pulley 16" dia. x 10½" face.
1. 24 K.W. 110 Volt, 650 R.P.M. D.C. Shunt Wound Motor, No. 2205, complete with slide rails and pulley 12" dia x 12½" face.
1. 19 K.W. 110 Volt, 600 R.P.M. D.C. Shunt Wound Motor, No. 2193, complete with slide rails and pulley 12" dia. x 10" face.
1. 15 K.W. 110 Volt, 600 R.P.M. D.C. Shunt Wound Motor, No. 2186, complete with slide rails and pulley 12" dia. x 8½" face.

The above mators all have starting boxes, switches and enclosed fuse out-cuts.

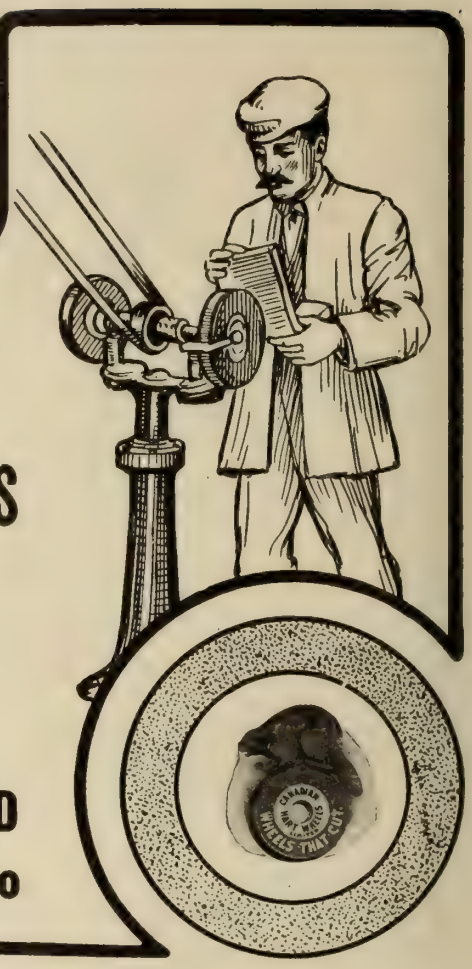
FREE INSTRUCTION BOOK

This book should be within instant reach of every engineer. It tells clearly, by photograph and formula, how to use the well-known Smooth-On Iron Cements in repairing boilers, engines, castings, tanks, joints, etc.



Used according to instructions, Smooth-On Cements will save more actual time and money in the engine and boiler room than any single product manufactured. Their uses are innumerable, and their repairs absolutely permanent.

Smooth-On Mfg. Co.,

JERSEY CITY, N.J.

For Sale by Supply Houses.

The Daily Grind

The daily grind of mechanics engaged in using abrasive wheels is made much more effective if their machines are fitted with

CANADIAN HART CORUNDUM WHEELS

Our wheels are free and fast cutting, porous, safe, and very durable. Send for our catalogue which describes the various processes used in making Canadian Hart Corundum and Emery Wheels.

Why Don't You "Get Acquainted" with this New Gap Lathe?

WE know it will pay you to find out ALL about it. There are many features which make it not only the most perfect gap lathe, but also the fastest in operation and adjustment. In fact, it exactly fills a long-felt want, and fills it so well that we are having difficulty in filling orders. We solicit correspondence in regard to it, as we know how good it is, and feel that if you also knew you would not be without it under any circumstances. These are some of the main points:—

Headstock construction prevents chattering, and deep oil chambers fitted with ring oilers make spindles and bearings self-oiling and always well lubricated.

Tailstock of a special type, and sleeve is clamped by a quick acting locking device. Tailstock is secured to bed by bolts adjusted from the top where they are easily accessible.

Bed, non-springing and webbed, and braced to secure rigidity.

Gap, vibration absolutely prevented by use of brace supports to carriage.

Spindle, high carbon hammered steel in solid chilled cast iron bearings, accurately fitted and self oiling.

Carriage and Apron, non-springing under severest strain, full "V" bearings and flat bearings in addition on front ways.

Double Back Gears give eighteen distinct spindle speeds, suiting lathe to work on widely different diameters

Compound Rest, with graduated base, accurately fitted taper gibs, end adjusted. Screws in both rest and cross slide read to thousandths.

Friction, Safety Feeds, screw and rod feeds cannot be both engaged at the same time. Quick changes of 1¼, 2½ and 5 times thread being cut.

Gears and Racks, cut from solid and steel where necessary.

Screw Cutting, full range of commercial threads provided for.

Equipment, Compound rest, steady rest, follow rest, large and small face plates, wrenches, two-speed, friction countershaft furnished with each lathe.

Accuracy, Strength, Solidity, Wear. These are the paramount features behind all McDougall Machines. Made **to meet extreme demands.**

POND REVERSING MOTOR PLANER

With Pond Patent Planer Control

13 Cutting Speeds **13 Return Speeds**

Pond 48 inch Reversing Motor Planer

The Reversing Motor is connected directly to the driving shaft---enabling the full power of the drive to be transmitted without loss to the table. The elimination of all slipping between motor and table gives an accuracy of stroke heretofore unattainable.

The Motor responds instantly to all speed changes which may be made while table is running at any part of stroke. This sensitiveness facilitates setting of work and tool.

The Pilot Switch, in itself, gives a slow speed irrespective of the position of the speed regulators on the controller, thus permitting the operator to slow down for hard spots or extra heavy cuts---returning immediately to the regular speed.

Variation of speed alone will show economy---the convenience, simplicity and perfect control of the speeds on the Pond Reversing Motor Planer increase that economy considerably.

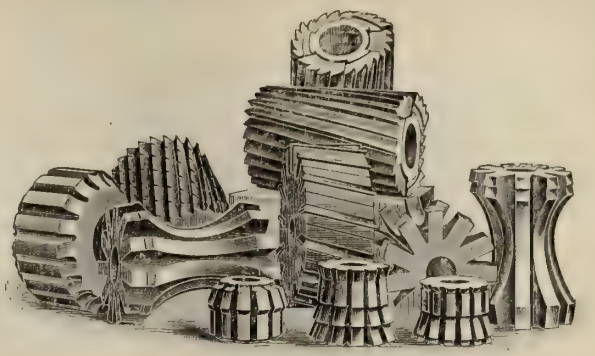
"Bemis & Call" Combination Wrench

is a strong and serviceable combination of a nut and pipe wrench, and is equally efficient in either capacity. It is a most convenient tool for any mechanic's kit.



The "Bemis & Call" Combination Wrench does the work of two ordinary wrenches, which means the saving of time and money.

It is made of the finest materials, head bar and shank being a one-piece steel forging. All parts are interchangeable.

Cost Reducing Features

An indestructible spindle bearing made of hardened steel and cast iron.

A head construction that gives more effective pulling power at the spindle than any other lathe built.

A patent "oompensating V" that permits four times the bearing area between the carriage and bed found on other lathes.

A carriage in which the tool thrust is taken on a bearing the entire length of the carriage, and which positively will not climb the V.

A double-walled one-piece apron which will last as long as the rest of the lathe.

A quick change gear complete in one unit, giving thirty-six changes with two operating levers.

An offset compound rest which can be used without skinning the operator's knuckles.

The centres set back of the middle of the bed, giving greater swing over carriage and permitting the turning of work up to the maximum swing without the tool overhanging the bed.

Chicago - Illinois

The Record Breaker in the Milling Machine Field

The Open Belt Drive on the New Model "C" Becker Mill ng Machine is one of the features that has helped to make these records of rapid, accurate milling.

The belt drive doesn't absorb power like the all-gear driven machines. It not only saves power and insures smooth action, but it prevents the constant vibration so noticeable in all-gear driven millers, due to the back-lash of the gears.

Practically all the work you have to do can be done on the New Model Becker by the use of the belt drive. And for extra heavy cuts, back gears are provided, which can be thrown in if needed.

Large direct spindle drives and wide double belts of high velocity, combined with powerful variable feed mechanism, and every convenience for operating, are enabling the Becker to break profitable production records in the milling field.

FOR SALE BY

THE GARVIN MACHINE CO.

SPRING AND VARICK STREETS. Visitors Welcome. 45 years in NEW YORK CITY.

The advertiser would like to know where you saw his advertisement—tell him.

The combination of the operator and his machine forms a production unit. The efficiency of that unit depends largely upon the handiness of the machine. On most jobs the operating time is longer than the cutting time. The handiness of Cincinnati Millers reduces the operating time. This feature is as important as heavy cutting capacity. That is why we have given it special attention in all our designs and have developed handiness farther than any of our competitors. : : : :

The 42-Inch Vertical Turret Lathe

MAXI-MILL TYPE

A development of the maximum possibilities of the Vertical Turret Lathe based upon a knowledge of the requirements gained by extensive observation and a specialized experience as makers and users thereof.

A machine tool of extreme power, having weight, rigidity and materials of construction to withstand the most severe usage continuously with a minimum of maintenance cost, and operative features of proven value in the reduction of production costs by the "elimination of wasted time."

18,500 POUNDS OF SELECTED MATERIAL—it is strong and rigid.

CHROME NICKEL STEEL GEARING insures high power transmission continuously without breakage or wear.

CONTINUOUS FLOW LUBRICATION eliminates power loss and increases machine life.

CENTRALIZED CONTROL permits the operator to concentrate on production.

Circular CV-42 goes into full details and will be mailed on request.

Kelly records 1200 hours, size and finish.

TYPE C FOR CYLINDERS

REPLACEABLE HIGH SPEED BLADES

Type C for Cylinders 3" to 12" diam.
Type B for Turret Work 1" to 5" diam.
Carried in stock.

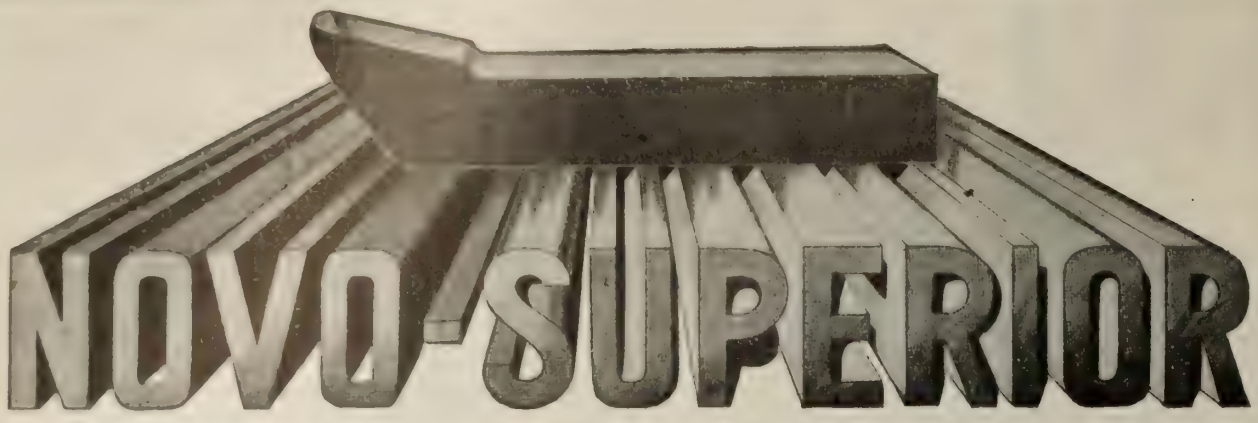
"JONES PAYS THE FREIGHT"

Dear Mr. Jones:-

If you will insist on having your engine cylinders reamed with a Kelly Reamer you will find that you will still have "Compression" long after "Mr. Smith's" EMERY-GROUND Cylinders are worn out; in fact, after his engine has run a month, you can "cut circles around him" out in the country.

THE REASON:-The old method-still used by some builders-was, to bore cylinders nearly to size and then GRIND them to size and finish, leaving the pores of the iron filled with EMERY GRIT-making "Emery-Laps" of both piston and cylinder from the start. The KELLY way is to bore the cylinder true to within .005", then REAM with the "floating" reamer, giving size correct to a TEN THOUSANDTH of an inch and an absolutely perfect surface, entirely free from emery grit.

The deduction is obvious, we leave it to you, get the right kind and your "freight bills" will be light.



Hoping this may be of service to you,
I am
Very truly yours,
W. E. KELLY, President.

The Kelly Reamer Co.

1555-7 Columbus Road (old S. Water St.)

Cleveland, Ohio.

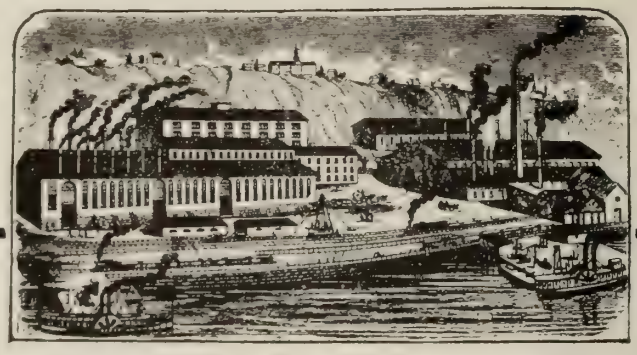
High Speed Steel Has a Solid Foundation In a Name That Means Something



Cutting speed attained on cast iron: Roughing cut, 140 ft. per minute—finishing cut, 210 ft. per minute.

In NOVO SUPERIOR you secure a materially increased speed over the high speed steels now in use, the highest quality, greatest toughness, longest life (3 times that of any other) and exceptional ability to cut very hard materials. The cutting edge retains its sharpness from 3 to 4 times longer than other high speed steels. Hardens in oil, air or water, and is now carried in stock in our warehouse in all current sizes, flat, squares and rounds; annealed and unannealed.

Blau-Gas For Welding and Industrial Purposes

CANADIAN COTTONS, LTD., CORNWALL.

"In reply to your inquiry of the 8th inst., we beg to advise you that so far the repairs you have executed for us have been satisfactory."

THE ROYAL LINE S.S. ROYAL GEORGE.

"At your request for a recommendation with reference to Blaugas, I would say that we have used your Blaugas and Oxygen for cutting out rivets and plates, and have found it extremely satisfactory. It is much quicker than any other method of cutting I have seen used, also it can be used in places where hand-work is impossible. I have much pleasure in recommending it to anyone requiring expeditious work of this kind."

THOS DAVIDSON MFG. CO., MONTREAL.

"We have your favor of the 31st ult., and beg to say that we have tested the boiler you welded for us and found it perfect."

WESTMOUNT AUTOMOBILE REPAIR SHOP.

"We are very pleased to say that the repairs which you have executed for us are in every way satisfactory, and the Welding Outfit and Process are certainly to be highly recommended."

THE STOCKWELL MOTOR CO.

"In connection with the brazing you have done for us from time to time on automobile parts, we have pleasure in stating that in each and every case your work has been absolutely satisfactory to us in every respect."

ERNEST SCOTT, MONTREAL, MACHINIST AND TOOLMAKER.

"Replying to your inquiry of May 31st, would say that the repairs, welding, etc., that you have done for me the last few months have been very satisfactory, and I expect to send you my future work in this line."

CANADA CEMENT COMPANY, LTD., PLANT NO. 1.

"In reply to your inquiry I beg to advise you that we had the Blaugas installed at this plant about three months ago. Previous to that we were using Acetylene gas, which was most unsatisfactory for Laboratory purposes. I find this Blaugus excellent in every way; it gives a very hot flame, has no harmful effects on Platinum, and gives no trouble whatever. I can thoroughly recommend it for use in any Laboratory."

CANADIAN REFINING AND SMELTING CO.

"The Blaugas outfit which you installed in our Laboratory we are using for Bunsen burners and blast lamps for heating purposes, and it is entirely satisfactory."

WESTON SHOE CO., LTD.

"As far as we can tell, the outfit installed by you is doing satisfactory work, and everything is in good state."

WABASSO COTTON CO.

"This is to certify that at the present time we are regular users of BLAUGAS, and same is giving us entire satisfaction."

MONTREAL COTTON CO.

"We are pleased to state that our trials with your gas have proven very satisfactory. Its heating capacity, compared with gasolene, is much superior. Knowing its qualities, we enclose you a contract for the instalation of two plants for our works."

HOLLAND VARNISH CO.

"In reply to your enquiry of April 22nd, we would say that the Blaugas plant you installed for us is giving every satisfaction. We have no trouble whatever with it, and as we are outside of the district for city gas, we naturally find it indispensable."

ALLIS-CHALMERS-BULLOCK. **TUDHOPE MOTOR CO.** **DOMINION TEXTILE CO.**
HAMILTON POWDER CO. **O. B. SHOW COMPANY.** **MONTREAL WATER WORKS.**

ONE HOUR'S WORK

WITH AN ELECTRIC WELDING MACHINE

THE BOY IS WELDING STEEL HOOPS FOR BARRELS

Sixty minutes' work and over a thousand in this pile (Count 'em.)

He places a hoop in the welder—the jaws come down and clamp the stock, the circuit is closed—the weld completed—the circuit breaker opens—the wire is released—all done automatically. Time: 3 seconds or 20 per minute.

It's a power driven machine requiring about half a horse power to run it. The speed can be varied from 15 to 30 welds per minute depending on size of stock. Can be used for a great variety of small work where it's the quantity that counts.

Figure the cost:	Current at 5c. per K.W. hour for 1,000 welds	.10
	Boy's time at 20c. per 1,000 welds -	.20
	Total for 1,000 welds - - -	.30

Ten thousand pieces per day at a cost of three dollars

This is only one of nearly fifty different kinds and styles of welders we make and if we haven't got what you need for your work—we'll make it. That's our specialty—building welding machines: good ones, of course, or we wouldn't be the largest manufacturers of welding machines in the country to-day.

By the way, our new bulletin is a text book on Spot Welding, or riveting without rivets, and it's yours for the asking.

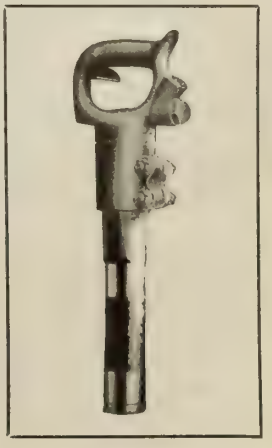
PNEUMATIC TOOLS



The absolute safety and simplicity of transmitting compressed air, its wide range of profitable uses and the economies effected by its uses, give it an indisputable position of supremacy as a means of transmitting power for operating small portable tools.

Pneumatic tools are not delicate, complicated pieces of machinery, but positively simple, rugged little money savers, made to stand rough usage, yet maintain their efficiency.

In "Imperial" designs wearing parts are reduced to the reasonable limit of simplicity, and manufactured to give the greatest satisfaction.

No part of a plant equipment, representing the same investment, will do more to reduce labor costs, increase output and enlarge dividends than a good pneumatic tool equipment. We firmly believe that "Imperial" tools represent the very best sustained value, first costs, maintenance and operating costs being considered. They are thoroughly well designed, embody all practical up-to-date improvements and give very exceptional efficiencies. These features have won for "Imperial" tools their present favored position.

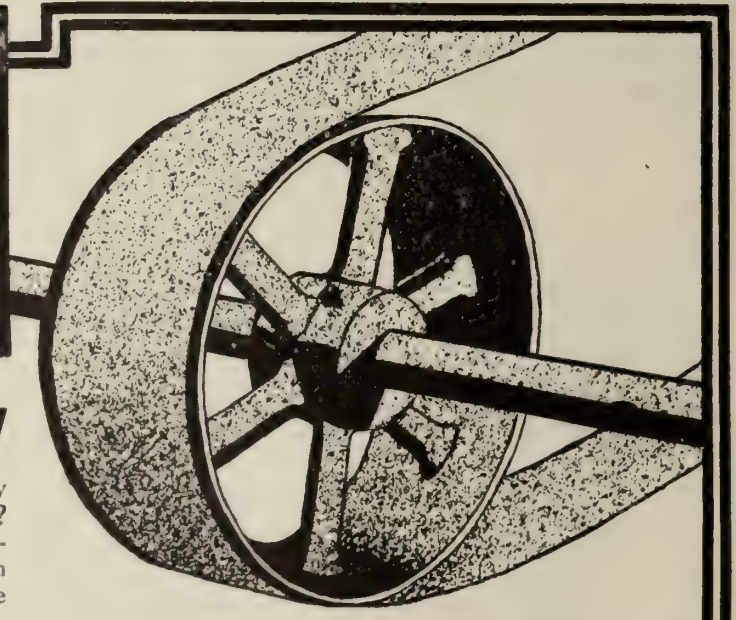
The PULLEY of TO-DAY---not of YESTERDAY.

The Passing of The Pioneer

Pioneers have to give way to later developments. Every dog has to take his holiday—to pass away into innocuous desuetude, or some such quiet place, wherever it may be. The gist of the argument is that pioneers pass away. Where they go the world little cares. Sometimes they repose in awful places like museums. But the world concerns itself with to-day, not yesterday.

Consider the first railroad train run on the American Continent. In the early thirties it was imported from England and made a trial trip out of Albany, N.Y. The engine was called "The John Bull" and would frighten a staid truck horse of to-day into hysterics, while the miniature coaches would disgrace a respectable cabby if he had to drive them through the back streets. How does such a relic stack up with a modern Canadian Pacific Limited train? Merely a historical recollection.



Thus in the pulley field, pioneers are passing away and the POSITIVE Combination Split Pulley is forging ahead, is away in the lead, because it is not an imitation, is different---an improvement, an advancement, a scientific development. It combines the high belt contact of a wood rim with the maximum strength and lightness of steel arms; then the malleable hubs permit of tightening to a vise-like grip without splitting, and the interchangeable cast iron bushings exert a positive compression on the shaft. No two-piece segments are used in the rims, which are waterproofed and have a lignum vitae finish.

The POSITIVE Pulley is in absolute balance, is built right---excels in materials and construction just as much as it does in design. The POSITIVE Pulley is the pulley of to-day, not of yesterday. You keep abreast of the times in manufacturing and you need in your shop the pulley that leads in the world to-day---the POSITIVE.

GOODHUE BELTS

Will Save YOU Money

Why have a large Belting expense account? Why not minimise this expense by using **Goodhue Belts?** They stretch from 15% to 25% less than other Beltings. **The Reason:** We have taken more care in stretching before the Belt is completed—none of the unstretched parts are ever used in the finished Belt.

Goodhue Belts have just the right amount of "Cling" on the Pulley, and the price at which they sell, combined with the satisfactory and lengthy service they give, make Goodhue Belts the lowest in cost on the market.

Goodhue Belts welcome comparisons, and the best comparison is a test in competition with your other Belts. **"Extra," "Standard" or "Acme" Waterproof Belts** suit all the varying conditions of use. Don't pay for belting that will prove an expense—our Belts are the dependable and guaranteed kind.

THE HEART OF A BABBITT METAL

THE United States Government made a radical departure from orthodox methods when they tested Magnolia, using water as a lubricant.

This test in connection with the tests they made, using oil as a lubricant, furnishes valuable comparative data.

For instance, in the oil test Magnolia showed only 25 per cent. superiority, antifrictionally; but in the water test it proved to be 200 per cent. superior to a high-grade babbitt of the conventional kind, and 1100 per cent. superior to white brass.

This demonstrates that a good lubricant will bolster up to a considerable extent even an ordinary grade babbitt, if plentifully supplied, but when water is used you get at the very heart of a babbitt, and prove its true inherent value. This is worth knowing, because the oil supply gives out sometimes, or the oil holes become clogged, or the quality of the oil is inferior.

Engineers who study these problems will realize that this wonderful showing of Magnolia was due to its very low co-efficient of friction. They also appreciate that a metal that does not become hot is not liable to squash, and wears very slowly.

We lay particular stress upon this quality of Magnolia, because it means safety and economy in every way, and minimizes loss of power.

OILDAG

(Registered Trade Mark)

Deflocculated Acheson-Graphite, Dag and Oil.

Graphite does not dissolve in any liquid or break under pressure, and these qualities, added to the unctious softness and purity, together with its non-coalescing nature, make Acheson-graphite ideal for lubrication purposes.

The process of deflocculation takes Acheson-graphite powder so fine that 99% of it will go through a sieve having 40,000 meshes per square inch, and sub-divides each grain of this finest powder into many still smaller particles—so small that they cannot be seen through a strong microscope.

Oildag is this deflocculated Acheson-graphite suspended in oil, where it neither floats or sinks, but is evenly distributed throughout. Oildag will flow anywhere the oil alone will go.

Mr. Robert A. Ross, E.E., of Ross & Holgate, Consulting and Supervising Engineers, Montreal, writes:

"As my firm are constructing and operating steam plants, we have wished to use a mixture of graphite and oil for cylinder lubrication, but have been prevented by the fact that the graphite settled out of the mixture. **This difficulty you have overcome,** and we are now assured of the best lubrication in the world, especially in superheated steam practice."

Process of Manufacture of Lap-Weld Wrought Iron Pipe

By Fred H. Moody, B.Sc.

The Methods Employed in the Manufacture of Wrought Iron Piping are Here Set Forth and Illustrated; Shewing Clearly the Difference in Treatment Adopted, Which Leads to the Two Well-Known Classifications, "Lap-Weld" and Butt-Weld." Users of Both Types of Piping Will Find the Information Instructive and Valuable.

THE Page-Hersey Iron Tube and Lead Co., have two pipe mills, one at Guelph, Ont., producing butt-weld pipe, and the other at Welland, Ont., manufacturing lap-weld pipe. With the process of manufacture of the latter particularly, this article deals.

Butt-weld and Lap-weld.

An explanation of the terms "butt-weld and "lap-weld" is contained in the following brief statement covering the initial preparation of the pipe stock. In the butt-weld, the sheet metal blank which forms the pipe is bent to circular form with edges butted at a welding heat, and afterwards rolled to make the joint. In forming a lap-weld, the edges are swaged before bending,and results with the overlapping of the edges when bent to the circle, in a weld surface of greater area and thickness as compared with the butt-weld. The Page-Hersey Co. make all pipe up to 2 inches diameter by the butt process, and for larger diameters, the lap process is adopted.

Lap-weld Process of Manufacture.

Following the process of manufacture from the beginning, the metal stock is kept in the yard adjoining the pipe mill, and arranged in piles of different sizes. It is called "skelp" and is especially made for this class of work, being rolled to the proper gauge, and cut to the proper width for rolling to the desired diameter with the necessary lap. A traveling crane covers this "skelp" storage yard, and also runs across the end of the pipe mill. One of the crane girders is shown at A Fig. 1. The crane carries the "skelp" in bundles of probably two dozen pieces, and deposits them in the pile B. on fingers extending from the wall which swing from it, and are operated by hydraulic hoist as desired. The car C moves in the same direction as the crane, and when empty, is run under the raised fingers supporting pile B. These fingers drop through openings in car C, and deposit the "skelp" on the car shown at D.

Furnace Mechanism and Operation.

On the right at E is the furnace for heating the plates, and in which a pile of sheets can be seen on close examination. Charging is accomplished by the low charging crane F which has about the same travel as the car C, and in which the operator sits, controlling the cross-travel of both, as also the charging finger. When charging is desired, the charging finger G suspended from a track on the charging crane, is run back, and the car C run up in line with it, the latter being first moved in line with the part of the furnace to be charged. The finger end (hidden by the laborer) is knife-edged to slip between the plates on the pile, and has a shoulder back from the end about eight inches, which engages with the plate and shoves it forward. Three plates are charged in a batch, the finger being then run back out of the way.

Heat is produced in the furnace by a blast of producer gas generated in three large producers located in an outbuilding. Natural gas, which is very abundant and cheap in the neighborhood, was originally used, but had to be given up, as the blast was found to be too sharp and intense. Producer gas, from its lower heat value, is not as sharp, and therefore more desirable. The blast is directed alternately from one side to the other, being changed every half hour, entering one side and leaving the other, and vice versa. The small levers H control this change over, and the large valve I controls the supply, which as shown, can be nicely regulated to meet requirements.

For the next operation a long bar J is attached to the end of the charging finger. The other end engaging with the top plate of the hot pile in the furnace, shoves it out at the end of the furnace A, Fig. 2, and runs it into the swaging rolls dimly shown at B. These swage the edges of the skelp, passing it on further to a table C. The operator on the left, hits the red hot plate in the middle of the end of the skelp bending the corners, so that it will enter the die D. This die consists of two steel castings bolted to the near end of the table C. The dies are formed converging slightly wider than the skelp width at the back, and taper down to circular form at this end. There is a space between the dies wide enough to permit the entrance of the tongs E, which grip the crimped skelp. The hook F of the tongs E is dropped into the endless, slowly moving forward chain G, and draws the hot skelp through the die. As it enters the die, a ball, the internal size of the pipe,is dropped in behind, and is held in place by hook H. The pipe comes through as shown, the edges overlapping, though not together. When completely through, the tongs are removed and the pipe is allowed to roll down the runway I which consists of several pieces of pipe on an easy slope. The other end of these is at A, Fig. 3. The rolling pipe is stopped by the trough B on the car C. The overhead

Fig. 1.—First Furnace and Skelp Charging Mechanism.

Fig. 3.—Second Furnace and Charging Mechanism.

part of the charging crane is stationary, with three running carriages for the charging fingers, one to each of the doors of the furnace E. All the control is from the control box D. The pipe is introduced into the furnace for reheating alternately through the doors on either side, and when heated sufficiently, an operator rolls it over opposite the central opening, through which it is shoved by the middle charging finger, to the welding rolls at the other end, A Fig 4

Rolling and Welding.

The rolls are of cast iron, about 30 inches diameter, turned out to the finished size of the pipe. The top roll is knurled at the bottom of the groove. On the end of the rod B is a chilled cast iron ball C the size of the inside diameter of the pipe. This ball, is run up by the mechanism at D. directly between the rolls, and leaves a space between the ball and roll grooves, of the thickness of the finished pipe. The pipe is now shoved through from the far side into the rolls, which force it over the ball die. The rod B. holds the ball die in place during the operation. Precaution is taken to always have the welding edge uppermost as it passes through the rolls. Thus the knurled face of the groove in the upper die comes on the line of juncture, welding it thoroughly; the small ridges of the knurled surface doing this more efficiently than if plain, and accounting for the knurled line apparent on the finished pipe. During this operation, the section of the metal is reduced to such an extent as to elongate the pipe about two inches per foot.

When completely through the rolls, the rod-moving mechanism at D. is set in motion, drawing the rod from within the pipe and sending it back on other rolls, one of which is shown at E. The die ball is left back at the rolls.

These die balls are frequently scored after operation, and seldom last for more than two dozen pipes, being sometimes useless after even one passage. The still hot pipe in the trough F. is lifted out by fingers on the shaft G. and allowed to roll down pipes H.

It sometimes happens that one passage of the rolls is not sufficient to thoroughly weld, and another passage is required; in which case the fingers I. are swung back, dropping the pipe into trough. By the turntable shown in Fig. 5, the pipe is swung around, so that it may pass through the rolls opposite end on. Rollers in the runback trough J. are set in motion, sending the pipe back to be reheated and re-rolled, both operations being as before described. In case re-rolling is not necessary, as is usual, fingers I. are left as shown, permitting the pipe to pass over the trough J.

Continuing reference to Fig. 5, the pipe passes into trough A; the view clearly showing how this trough is aligned to be central for the rolls by means of screws shown at B. The trough at the welding rolls is similarly arranged, allowing of adjustment to take any size of pipe. To the left is shown the turntable previously mentioned in connection with Fig. 4. for running the pipes back for re-welding where necessary. It is essentially an hydraulic jack which lifts the pipe above the runback trough, and permits of its swinging around end for end. The pipe after leaving trough A. passes through the sizing rolls C. while still hot, which brings it down to exact size, after which it is rolled along a trough on the other side of the sizing rolls till it comes to the cross rolls A. Fig. 6, which are elliptical and are placed at an angle of about twenty degrees with the axis of travel. This gives a rolling, as well as longitudinal motion to the pipe, accounting for the spiral score marks to be found. The pipe which is still a bright red, is given several passages back and forth, after which it is lifted out of the trough B. by fingers in slots C. on to the cooling table, up which it travels slowly by moving chains; being cool enough to handle by the time it arrives at the top, where it is rolled on to a long table. The cooling table is the pride of every operating engineer, and the one shown is one of which S. Hall, superintendent of the pipe mill might well be proud

Fig. 5.—Sizing Rolls Shewing Turn-Table.

Fig. 4. Welding Rolls and Run Back.

Fig. 6.—Cross Rolls and Cooling Table.

From this table the pipes are taken individually and straightened under a heavy press, after which operation, they pass into the machining room, where the rough ends are cut off. The pipe is then threaded and tested under hydraulic pressure. After putting a pipe connection on one end and a protecting ring on the other, the pipes are ready for shipment.

Degrees in Engineering

By Joseph Horner.

THIS article is from the pen of Mr. Joseph Horner, the well-known engineering writer and author, and was contributed in the form of a letter to a recent number of the "Times Engineering Supplement," London, Eng., as a reply to a previous article by Dr. Fleming in the same journal. Mr. Horner gives the factory point of view, and what he says will doubtless be read with interest by a large circle of readers holding like or contrary opinions. Proceeding, he says :

"Dr. Fleming's article raises a question which has long exercised the minds, and even appealed to the sense of humor of the men who do the rough work of engineering. Compare the strenuous life of men engaged in the factory and on public works with that of the class-room. Those whose lives are occupied in these constructive works know well how little real aid is to be derived from pure science beyond elementary principles, with sufficient arithmetic and mathematics to apply those elements to practice. The men who have been most successful, men who possess and know how to apply this elemental knowledge, would not have scored so well, often probably they would have been sad failures, if they had qualified at Universities for degrees before commencing practical work.

Radical Difference of Training.

"The immense and radical difference between the training of the Universities and that of the shops can hardly be appreciated by a University man. It is nearly impossible to do so, because the atmosphere of one differs so totally from that of the other. The engineer who is the product of the text-books is not the man who can construct an engine or machine, or lay foundations, or build a bridge, or run an Atlantic liner, or build up a flourishing business, or rescue a decadent business from bankruptcy. All the rules have to be modified before they can be translated safely into practice.

"The real life of the successful factory is strenuous, the hours are long, there is no such thing as leisurely labor, attention has to be concentrated, myriads of difficulties which are never suggested in any text-book, and which all the text-books written in the world would never contain, have to be met and surmounted with promptitude. Money has to be made ; and a slight difference in the cost of production, and a few pounds more or less in the figuring of a tender, will throw the work into the hands of a rival at home or abroad. Many little economies total up to big aggregates. They include choice of designs, one being probably quite as suitable as another, but the simpler is selected by the experienced manufacturer. They include little economies effected in all the shops —in foundry, smithy, plating shops, and in methods of tooling in turnery and machine shops. It is along these lines that keen firms make money. But no text-book attempts to explain these things, no professor teaches them ; they can be understood, or even appreciated, only by a man who is thoroughly versed in the methods of all the shops which collectively form the engineers' works, which knowledge only comes after many years of close observation and experience.

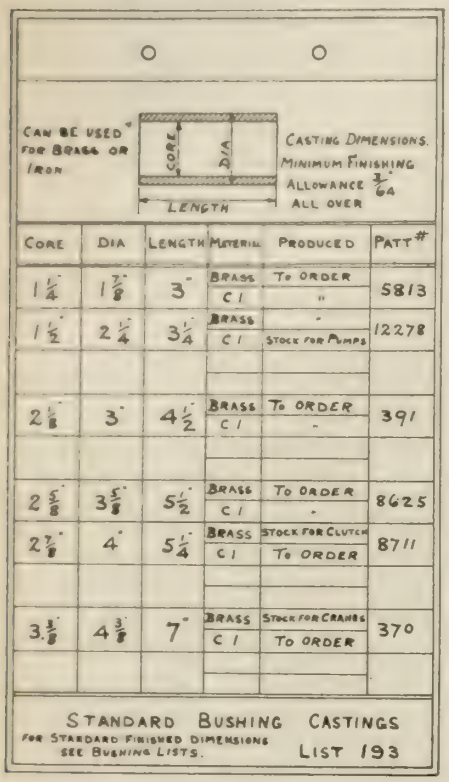
The Highly Scientific Training.

"The claim is often made that a highly scientific training is necessary to the making of a scientific engineer. By this somewhat vague term is understood the man who is able to scheme and design and complete mechanisms or works ab initio, an originator, a creator. But there are no such men. Every great triumph of engineering is the work of many minds and many men, in which theory has to be brought to the test of practice. We see it going on to-day in aviation ; we are familiar with it in the case of machine tools, of locomotives, of steam turbines, of gas producers and gas engines, and much else. How very small a section of the growth of any one of these is the product of the colleges, how much is due to the men who manufacture ? Granted that the higher education is desirable, and may be necessary for the pioneers in engineering, the great harm which is done by turning out so many young men equipped with degrees is that hopes are raised which can never be materialized, because the supply vastly exceeds the demand. In a works employing a thousand hands not half a dozen such men can find employment. The ordinary draughtsman has no scope for the exercise of that training, neither have the departmental managers and foremen, certainly not the workmen. The students who are turned out of the colleges year by year will be sadly disillusioned as they come to middle age and find themselves occupying very subordinate positions. The effect of this kind of training is already becoming apparent in the unpractical character of too many of the articles which appear in technical journalism, and which are read before the engineering societies and published in their proceedings. Highly mathematical, tediously experimental, they miss the living features which would appeal to the manufacturer whose horizon is, and must be, bounded by the solvency of his firm. Engineering studies are becoming far too academic in character.

Less College and More Shop.

The writer, who went through the mill in the old-fashioned seven years' apprenticeship, thinks that the old training supplemented by short technical courses which were not then available is the true remedy. There must be less of college and more of shop. If the pupils who went through the shops had been privileged to sandwich such short college terms in the period of their pupilage there would not have been so large a percentage of "Wasters" turned out as there unfortunately were. The point is that the permanent set must be taken in the shops, not in the colleges, and therefore professors should be men who have already made a sound reputation in the workshops and on the erection of public works—engineers primarily and professors afterwards. They would then be qualified to teach essentials, to point out the difficulties that arise and explain how they may be surmounted, to deal with the financial side of manufacture as it occurs in a hundred aspects in every department, to put hypothetical cases as in medical examinations, and so test the aptitude or experience or originality of a man. This would develop the faculties that men have to exercise every hour of their lives in the shops.

Standard Lists.



By Harold Smith, Toronto.

THE importance of standardisation must have occurred to manufacturers in the very earliest days of engineering. More especially in the usage of such common articles as screws, bolts, etc., would their minds turn to the possibilities of having a standard thread to obviate the unnecessary delays and expense incidental to so many bastard styles. Finally, of course, as we all know, our ancestors got together and agreed to use a definite standard, with enormous resulting economies. In a similar way almost all large firms are nowadays considering the standardisation possibilities in their factories, by means of which duplicates of small parts may be obviated, and the variety of styles minimized. Standard lists are generally recognized as the most practical way of accomplishing this and maintaining it.

Object of Sample Lists.

Good samples of lists are shown in the accompanying cuts. The object is to

place before the designer in as compact form as possible the particulars of standardised items, so that he may pick out details for which his firm has patterns, tools, jigs, etc., and without which information he is liable to design articles varying in unimportant particulars from what has been already

LIST 193

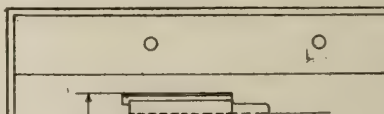
made, but still sufficiently different to warrant perpetual capital expenditure. This is likely to occur in a large drafting office having several sections dealing with different kinds of machinery; one section being unacquainted with the details of the others. It may also occur in each section over a period of years, as changes of staff occur (due to men leaving) and their successors having no ready means of acquiring the knowledge of what has already been done.

Consider for instance bushings. What a multitude of patterns of all lengths and bores must firms accumulate on their shelves. Also consider that a standardization system would have kept their number down 50 per cent. or 25 per cent. Some of these patterns may be used but once. Standard lists properly looked after will prevent duplication of design as well as create a call for standard parts from all departments. Careful watching will soon show that certain items are in continuous demand, and will enable the storekeeper to order such parts and have them machined in stock quantities, instead of one or two at a time as required. The possibilities of saving in production are obvious. When this stock system has been established, there is a positive connection between drafting room and stores, also the stock carried by the latter is live. Moreover, the amount of money invested in stock will be reduced, as it will be constantly turning over.

Formation of Lists.

It must be fully appreciated that a standard list is not a mere tabulation of all the sizes and varieties that could possibly be used of any article, but a list wherein these varieties are boiled down to the lowest possible number. For instance in the case of studs, it would not effect any economy to have a list running from 2 up to say 6 inches length, by steps of 1/8 inch unless every different length was necessary. The essential idea is to enumerate only those pieces which have been found to be called for right along. Such lists can be started gradually by taking different articles one by one and careful analysing existing designs. Do not make out a theoretically correct list and try to apply it, ignoring all past and existing designs, as this would be expensive and cause endless trouble. Build on what has been done, and eliminate duplication gradually. It will take time and a lot of trouble, but it is worth while. No general rule can be made as to what should be standardised; every firm must judge that for itself. Standard lists of drills, reamers, jigs, gauges, milling cutters, hobs and boring bars can be made in a similar way to great advantage, enabling the designer to make use of existing tackle, and establishing close connection between drafting and tool rooms. Moreover it means that to some extent a job is mentally planned and routed as to operations in the shop before ever it leaves the drawing board.

Standardization and Efficiency.



Do not sacrifice standardisation to efficiency, but once established do not depart from it. Additions to list should only be allowed by sanction of competent authority. No firm need think their product too varied for this standardisation of details, in fact such conditions will show up the value of the system most.

Many firms do not have standard allowances for fits in round holes. All holes should be made standard size and outside diameters turned, or according to fit required. This means that reamers, boring cutters, etc., can be kept in tool stores ready for any job. In this way, castings which previously were bored in the engine lathe and finished off a mandrel (because quantity was small and foreman did not consider the expense of a reamer warranted) become a turret lathe job, with resulting economies in production and accuracy.

If fits are allowed for in the opposite way by making outside diameters standard and holes plus or minus according to fit, standard reamers, etc., become impossible, as 3 or 4 of each size would be required, varying only a few thousands from one another. This also applies to gauges. Outside diameters, being produced by lathe or grinder and being gauged by micrometer, do not require different tools for each size. Turret lathes, the most productive machines we have, are too often looked on by the management of a shop doing a general business as too specialized for their work; yet standardisation on the lines mentioned, makes them as sound comparatively for jobbing as for specialized production. Further the tool room equipment in reamers, gauges, boring cutters is not expensive when once standard lists are in use, and their principles embodied in designs before they leave the drawing board.

Standard lists are not a cure-all, but it is surprising how far-reaching are their effects when properly established and maintained, and how many small economies will come naturally and easily from their use.

The writer is intimately acquainted with two large old country firms who have made them features of their factory organization, and both consider them to be the only satisfactory way of economically producing a varied product. One firm manufactures a very large variety of machine tools, and the other a still larger variety of general machinery. Their lists, started in a small way, now run from 300 to 400 sheets, being increased more and more as their utility became apparent.

LIST 119

The Department Plan of Machine Tool Arrangement*

By C. B. Auel**

A Discussion of the Question of Manufacture on a Basis of Tool Arrangement as Compared With Manufacture on a Basis of Product. Mr. Auel Shows That the Growth of a Large Manufacturing Concern Sometimes Warrants a Change From the Former to the Latter, in Order to Effectually Cope With Orders.

IT WILL be found almost invariably that in the orignial design and layout of small and medium-sized manufacturing concerns, the tool equipment has been so arranged as to group together operations of a like kind, such as milling, planing, drilling, boring, screw machine work, etc.

The reasons for this are:—

(1) That for each of the principal machining operations, there is frequently but a single expert and in order to make the best use of this talent, no other scheme is permissible.

(2) The centralizing of machines of a kind tends to decrease the number required for a given output.

As a result of these there follows logically:—

(3) Accuracy and speed in workmanship.

(4) Uniformity in method.

(5) Economy in floor space.

(6) Minimum distribution of power.

Feeder and Assembly Sections.

Under this method of production, a shop may be said to be divided into two portions, "feeder" and "assembly" sections respectively, the "feeder" sections making the parts from the raw materials and delivering them either to storerooms or to "assembly" sections where they are assembled into the complete apparatus preparatory to test and shipment. There will in general, be a number of "feeder" sections, entirely independent of one another and there may likewise, be one or more "assembly" sections. A production, planning or routing department usually determines the manner in which orders are to be brought through, arranges delivery dates, keeps track of the orders as they progress through the shop and exercises general supervision over production.

The East Pittsburg plant of the Westinghouse Electric and Manufacturing Co. was operated until about three years ago, along lines which may be said to have been departmentalization partly on a basis of tool equipment as outlined and partly on a basis of product, during which time it met conditions fairly satisfactorily. However, in any growing manufacturing concern, there comes a time when the advantages of the preceding arrangement are more than offset by the difficulties incident to its successful operation. The increase in volume of semi-finished parts passing from "feeder" to "assembly" sections, with the accompanying increase of clerical and other work and the multiplication of foremen and superintendents concerned in the manufacture of any one class of product, result in delays and increased expenses of various kinds which cannot be overcome, nor can the recurrence of them be prevented.

Inability to Fill Orders Promptly.

Perhaps the greatest drawback of such a scheme is the inability to fill orders promptly. This is especially apparent during periods of business depression when quick delivery is of larger importance than at any other time. The amount of stock on hand is then usually lowest and accordingly a larger percentage of apparatus requires to be built from the ground up, to fill customers' orders. Under these circumstances, it becomes imperative to place so-called "rush," "forfeiture" and other orders of a like nature in a class by themselves and to conduct them personally, as it were, through the shop. In the doing of this though, other orders are relegated to the back-ground with consequent disastrous results particularly in the matter of dissatisfaction on the part of the customers for whom such orders are intended. Of course, the greater the volume of these special orders, the greater the ensuing confusion and delay in connection with others, so that this method of procedure is not a solution of a difficult problem but simply a makeshift, a temporary expedient, to be abandoned as quickly as some more rational method presents itself.

Another vital difficulty perhaps equal in importance to that already mentioned, is the matter of divided responsibility, no one individual being primarily responsible for any complete piece or class of apparatus. Such being the case, it is exceedingly difficult even to make an attempt to ameliorate or to improve conditions which are known to need attention, for the reason that there seems to be no proper place at which to commence the betterment work. As a result of these conditions and without going any more minutely into an analysis of the difficulties, it is reasonable to assume that in consequence of shipments being delayed and responsibility divided, "work in progress" and "stocks, raw and finished" will be high.

Factory Departmentalization.

Recognizing that methods of manufacture which had in the past been satisfactory for their needs, were, for the reasons already stated, proving inadequate to handle the increasing volume of business, the Westinghouse Electric and Manufacturing Co. spent considerable time in investigating the methods of other large companies in similar lines of business, with the result that it was deemed advisable to modify the original scheme in favor of so-called "factory departmentalization"; that is, to divide the plant into a number of separate units, as self-contained as the nature of the work of each would permit; in other words, to treat the units like independent factories, housed together under the same roof for mutually advantageous purposes, yet buying from and selling to one another their various commodities as circcmstances made desirable. A scheme of this kind naturally causes a number of duplications of the organization and equipment. While this is so, it does not necessarily involve any material increase in either, since the change is more in the nature of a re-arrangement of the existing equipment and organization, with the addition here and there of a few tools which under the original plan, were used in common by two or more departments. Even this may to some extent be avoided by assigning such tools to the department requiring them most and permitting the other departments to have their work done on requisition.

In introducing this scheme in the East Pittsburg works, it was deemed advisable as a precautionary measure to put it into effect in but one department only, further progress along this line to be dependent wholly upon the results obtained. This was accordingly done and with very gratifying results, almost from the very commencement. It was found as anticipated that among other advantages, shipments were facilitated and "work in progress" and "stocks" decreased to a very marked degree.

Comparison of Plans.

Comparing the routine in this particular department under the original and the modified plans, in the former the work was performed by 22 sections located in 13 independent departments: in the plan as modified, the same work

---

* Paper read at the National Machine Tool Builders' Convention, Atlantic City, May, 1911.

** Asst. Works Manager, Westinghouse Electric & Mfg. Co.

is now done by 13 sections in 7 independent departments. This, however, by no means emphasizes the difference even in the routine, for the reason that under the modified plan authority for an entire line of product is vested in a single individual, who therefore, is enabled to exercise his discretion as to the raw and partly finished items to be carried. By a judicious selection of these, he has at all times a certain amount of stock on hand and is thus to a large extent not dependent in the matter of deliveries on the other sections outside of his authority which supply him with materials.

As a consequence of the excellent showing made in the department selected for trial, departmentalization was gradually extended throughout the plant until now the work has been almost completed. Though not yet perfected, the general results have been a confirmation of those obtained in the department in which the scheme was first tried.

Departmentalization Not Always Practicable.

It is hardly practical to carry this departmental idea into all sections; for example, in the pattern shops and foundries, or in certain other places where either the work or the equipment is very special; neither has it been deemed wise to include disc grinding or polishing on account of the deleterious effect of the dust and fumes on other machines in the vicinity, though certain work of this kind is being done in some of the departmentalized sections where facilities for carrying off the dust and fumes have been provided.

As at present arranged, there are in the Works eight fairly self-contained departments as follows:—

(1) Railway, Mining and Crane Motors.

(2) Power—for large generators and motors.

(3) Control—for railway and industrial control apparatus.

(4) Detail—for switchboards and accessories.

(5) Small Motor—for small power motors.

(6) Transformers.

(7) Locomotive.

(8) Industrial—for medium size motors.

Besides these, certain "feeder" sections still continue: coils, punchings, blacksmith, cabinet and pattern-making, screw machine, foundries, etc.

With respect to the screw machine section, it may be stated that this has been departmentalized to some extent, though the greater portion, for the manufacture of such parts as are made in large quantities and carried in stock by the central stores remains unchanged. Regarding the other "feeder" sections, it is possible that some of them may in due course be departmentalized, without necessarily changing their present geographical location; but simply by assigning a certain proportion of the floor space and the tool equipment in each, to each of the already departmentalized units.

Advantages of Departmentalization.

The results obtained in the other departments have been as already stated, but a repetition in greater or lesser degree of those in the department where the modified plan was first tried out. Summarizing the various advantages they may be said to include:—

(1) Centralizing of authority in the production of each class of apparatus.

(2) Decrease in time required to fill customers' orders.

(3) Increase in output in a given period.

(4) Decrease in "work in progress" and in "stocks".

(5) Saving in floor space.

(6) Decrease in handling of materials.

(7) Decrease in clerical labor.

(8) Decrease in indirect expense in overhead burden

(9) Increase in individual initiative.

(10) Healthy competition between similar sections and departments.

In the matter of accounting, departmentalization has been carried even further than it has with the manufactured products, for every part of the works whether a "feeder" section or a complete department, is now self-contained in this respect, giving a total of 53 such units in all. These being comparatively small, permit the ready compilation of the transactions of the preceding month, so that all inter-sectional and inter-departmental accounts are therefore balanced on a monthly basis. A further advantage of this feature is that each unit has its own percentage of indirect expense or overhead burden, figured on its total productive labor which percentage is changed from time to time as circumstances seem to warrant. Order costs are compiled by the "feeder" sections and departments themselves. It may be stated that it is not the aim to show either a profit or a loss in any of the sections or departments, so that when either of these conditions arise, the overhead percentage is altered accordingly. Every month each of the units in the works is provided with a set of charts or curves giving a continuous record of its performance in total productive labor, total expense labor and total expense materials, the expense items being also segregrated along various helpful lines, all shown directly in dollars and cents and many as a percentage of total productive labor as well. This percentage is considered as a measure of the expense labor and material efficiency.

Scope of the System.

Regarding systems of wage payment, day work, piece work and premium work are all used, in the proportion at the present time of 35, 14 and 51 per cent. respectively. Time limits and piece work prices are set by duly qualified experts and only after careful consideration of all the factors involved. In determining these a base is first set which base is assumed as the time required to do the work by the average skilled workman working regularly as he ought to work. To this base time an incentive is added depending upon the class of work, surrounding conditions, prevailing day rates in the district, etc., which total time then becomes the time limit in the case of premium work; or from it is figured the piece work price where piece work is used. Upon the completion of each job, the actual time taken is compared by the time clerk with the base time and if the former is in excess, the matter is further investigated. In one of the departments, all time slips in each section at the end of each pay are totalled twice, first, with reference to base times, second, with reference to actual times; the ratio between them being the efficiency of the section as far as productive labor is concerned. This scheme applied to a workman's time slips, will likewise give the individual efficiency and was originally so used it is believed, by Harrington Emerson. It is possible the scheme may be applied generally in due course.

Departmentalization on the basis of product has likewise been extended so as to include the engineering and to a somewhat lesser extent the sales correspondence departments; in fact, in certain instances the engineers and the correspondents are located alongside of one another with the result that much of the routine work in connection with orders is facilitated.

In conclusion it will be appreciated that in what has been said within the limits of this paper, only the barest outline has of necessity been given of a few of the present methods of working of the Westinghouse Electric and Manufacturing Co. from the viewpoint of departmentalization on the basis of product. It is not intended in any sense to convey the idea that this method of operating a large and growing manufacturing concern is the only correct way; but, from the experience of our company, it is quite evident that it is the best method for its particular needs. No general statement can be made as to when it would appear advisable for a similar concern to change over from manufacturing on a basis of tool equipment to manufacturing on a basis of product, as experience alone would seem to be the guide.

Machine Shop Troubles, Happenings and Improvements

By Blackrock

Affording an Opportunity for Readers to Keep in Touch With What is Being Said and Done by Their Confreres. A Record of the Light That is Being Thrown on the Elements of Design, Constructional Detail, and Operation; the Daily Troubles Arising, the Difficulties to be overcome, and the Remedies Suggested.

TWIST DRILL GRINDING.

By H. N. Harding.*

I PROPOSE to first take up the grinding of the different kinds of twist drills, stating the grain and grade of wheels that have been found to be best suited for the work together with the results of various tests that have been made.

As the ordinary carbon steel drill is perhaps the most frequently seen and used, we will consider this first.

There is ordinarily from .020" to .025" stock remaining on the part of the drill to be fluted and from .010" to .015" on the shank if it is tapered, when the drill comes to the grinder from the lathe. The first operation is the roughing of the part of the drill to be fluted removing from .008" to .010" to a limit of from .002" to .003." This operation is necessary that the drill may be held securely in a bushing to be fluted, and you will readily see that as a good finish is not necessary, the wheel best fitted for this work is one that will remove the stock quickest.

It has been found that the 24 combination L wheel is well fitted for this work—fifty-eight 1 1-16" drills being ground in an hour, .010" to .012" stock removed to a limit of .001". The 24 combination M wheel is also used on this class of work.

I have found personally that the tendency of the operator is to use the hard wheel because he says it "stands up" better and he does not have to true it so often, and this by the way is a thing that the average operator seems to hold as a last resort.

A little aside from the subject, but I had an experience recently that illustrates the point very well. I called at a certain factory to start a machine and found that while they had been running it for a week, the operator could not remember that they had trued the wheel more than twice. When I trued the wheel twice for every arborful (they were grinding piston rings) they said they thought it would wear the wheel too rapidly, but as the time was more then cut in two, they thought is "helped some."

To return to the subject: the next grinding operation is the finish grinding of the flutes and shanks of the hardened drill. This is really two operations, but where two machines are operated by one man, one is set up for grinding the flutes and the other the shank.

I have personally found that the 24 combination K wheel gives the best results on the flutes. For this work a 14" x 2" x 5," 60-80, grade K, has also been used and sixty-six $\frac{1}{2}$" drills per hour, thirty-two $1\frac{1}{4}$" drills per hour and twenty-one $2\frac{1}{4}$" drills per hour have been ground complete, meaning both flute and shank; one operator running two machines, one on flutes and one on shanks, removing .008" to .014" from the flutes and .010" to .015" from the shanks to limits of .0025" variation in diameter, and 1-32" to 1-16" in length of shank. A 1-4" x $1\frac{1}{2}$" x 5", 60-80-M wheel was used in grinding the shanks.

Regarding the grinding of high speed steel drills it has been found that a little more than two-thirds of the work can be done on high speed steel that is done on ordinary carbon steel. This is borne out by the fact that with one operator running two machines with .010" to .015" to remove from the flutes and .010" to .012" to remove from the shanks, forty-five $\frac{3}{4}$" high speed steel drills were ground in an hour to a limit of .0005" in diameter and 1-32" variation in length of shank. A 24 combination L wheel was used for this work.

I have noticed that in finish grinding the flutes where finish is quite an important feature, that if the wheel is too hard the work will show a burned appearance just where the fluting stops, due probably to the fact that the wheel has become glazed or is trued too fine, and while it cuts all right on the flute where there is a clearance for the wheel, immediately it comes in contact with the full diameter of the stock, the pressure of the wheel on the work is greater and therefore this part of the drill will be burned.

I have purposely left the grinding of flat twist drills until last because we have had less experience with this line than the others. They are much harder to grind as a rule, for the material is such that if it is overheated during the grinding process the edges of the drill will check and crack and the drill will probably prove worthless. We ground some of these drills at the factory some time ago, the grinding being witnessed by the customer's superintendent. After grinding these drills were subjected to a test of being dropped a distance of four feet to a cast iron block. These drills were straight shank drills and in the test mentioned 1-16 in. stock was removed from the diameter of the work to a limit of .0005 in. at the drill point. One operator ran two 6x32 in. machines with the following result:

No. of Drills.	Diam.	Time.
48	9-16 in.	1 hr. 48 min.
27	5-8 in.	1 hr. 15 min.
20	$1\frac{1}{4}$ in.	2 hrs. 15 min.

(Two drills broke in each of the above tests.)

In another instance, twenty-five $\frac{5}{8}$ in straight shank flat twist drills were ground in one hour, removing $\frac{1}{8}$ in. of stock to a limit of .0005 in. at the drill point, one operator running two machines. The wheel used in this case was a 24 combination M.

* Norton Grinding Co., Worcester, Mass.

TESTING BABBITT METALS.

AN elaborate test of six samples of babbitt metals was recently made in England by a professor of engineering, assisted by a metallurgist, and was published by a prominent engineering journal occupying six columns with charts, tables and photographs. They gave the formula of only one of the metals; a "genuine babbitt," and were apparently satisfied with the statement that the other five samples contained varying proportions of lead, or words to that effect. It is fair to presume that these five samples were simply an ordinary batch of babbitt metals of different proportions of lead, tin and antimony and perhaps a little copper.

Purpose of Test.

The test was made for compression, tension, hardness, bending, impact and micographic. The summation of the test was expressed in the statement that all the samples withstood a greater stress than would likely have been put upon them in actual service. They did not give out a single test showing the anti-frictional qualities of these metals or the comparative values from the co-efficients although the gentlemen conducting the test must have appreciated the value of such figures and also of giving formulas by which comparative figures would show the relative values of the different compositions.

Anti-Frictional Qualities Overlooked.

They must have had some message to give out to the public in having made and published this test, but we doubt if its value will be apparent to the ordinary layman for lack of details regarding the metals. Had this information been supplied it would have been interesting and instructive as far as it went, but any experienced babbitt man knows that mere hardness in a babbitt metal expresses only a comparatively unimportant phase of the conditions to be met and are requisite in practical use. In fact, the very ingredients that harden a metal if used beyond a certain quantity, impair its anti-frictional qualities and it is therefore more liable to heat and run out of the box. The average shaft is so designed that it rarely, if ever, imposes upon the bearing a greater weight than it can safely sustain; in fact there is usually a large factor of safety, as the ordinary babbitt under compression test will sustain a weight of four or five tons per square inch.

What is it then that ordinary mortals want to know or ought to know about babbitt metals? Is not the whole story that is worth while told by a test that shows the comparative values of babbitt metals from the co-efficients? It certainly ought to be, if the tests are made properly, for such tests will of necessity show the value and capacity of the metals under varying loads and speeds up to their maximum capacity. Such tests should also be made with lubricants of different viscosities and also with water as a lubricant, if metals will stand the water test—for it is well to know how a metal will perform in case the oil supply gives out or the oil holes becomes clogged. Lubricants, particularly of high viscosity, interpose a thin film between the shaft and the bearing and will bolster up to a considerable extent a very ordinary babbitt, but when you come down to the water test, you get at the very heart of things and it will give you the true basic anti-frictional values of the metals tested. It is a case with babbitt metals of in aqua veritas.

Babbitt Troubles.

Probably 90 per cent. of babbitt troubles are due to frictional heat, sometimes complicated by initial heat and if a metal lacks anti-frictional qualities, what availeth it to be hard, as hardness will not prevent it from heating and squealing, in fact it will run out of box much quicker than will an anti-friction metal that might show considerably less sustaining powers under compression test. There is a great deal of misinformation on the subject of mere hardness in babbitt metals and there are engineers and mechanics who still form their opinion of a babbitt by whittling on it with a pocket knife. It is axiomatic that if a metal heats readily it is due to frictional resistance and that frictional resistance is caused by the interlocking and tearing apart of the two surfaces in contact. This waste of power causes a greater consumption of coal, lubricants and metal; it necessitates more frequent rebabbitting, and there is the liability of "shut downs" and overloading the boilers.

The economics and safety from using a high grade anti-friction metal on all bearings are so apparent that it would seem unnecessary to offer any argument in its favor or to point out that it is poor economy to use an ordinary grade babbitt merely because of the initial saving in cost. Where accurate figures are kept in a factory of all items of expense, it will not take long to demonstrate the economy and other desirable features of using a high grade anti-friction metal that will show a low co-efficient of friction particularly if it will stand up under a water test.

Description of the Gardner Crank-Pin Turning Machine

From "Engineering"

The text and illustrations refer to a specially designed tool for the rapid and accurate machining of crank-pins. The designers being under the necessity of using large numbers of cranks for gas and oil engines, experimented largely, and as a result this tool was evolved, giving results which completely justify, they think, the time and money spent.

The chief principle involved in the method adopted in this new machine is that of actually "forming" the crank-pin by means of a tool the full width of the crank-pin. To render this method of turning possible a positive drive, as close to the crank-pin as possible, is absolutely necessary, and this is one of the features of the design. A general perspective view of the machine is shown in Fig. 1, while Fig. 2 shows a crank in position. Figs 3 and 4 are two views of a crank, with reference letters for dimensions.

Detail Description.

It will be seen that the headstock drum or spindle carries on its outer end a large helical gear-wheel, which is driven by a pinion on the end of the main spindle of the gear-box. The main drive to the machine consists of one pulley only, 16 in. in diameter, for a 4-in. belt, the pulley running at 350 revolutions per minute; all speed variations are obtained from a system of gears carried in a gear-box mounted on the headstock. This gear-box gives eight speed-changes, arranged in geometrical

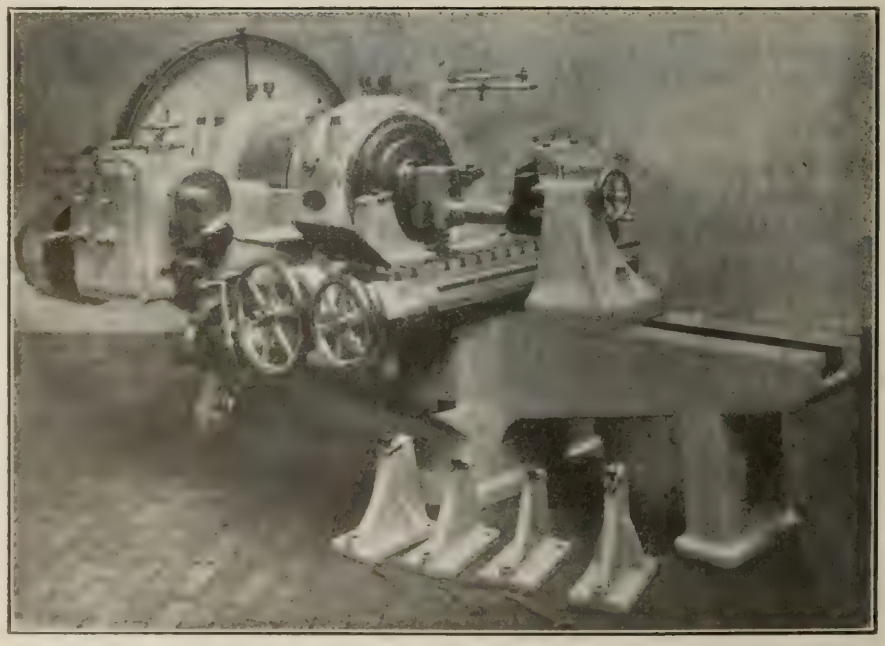

Fig. 1. Crank Pin Turning Machine.

progression, the speed-changes being obtained by means of interlocking levers; these levers prevent the possibility of two speeds being simultaneously engaged. All gears are of ample width and diameter, and have carefully cut teeth of special shape to ensure quiet running, and they run in an oil bath. As

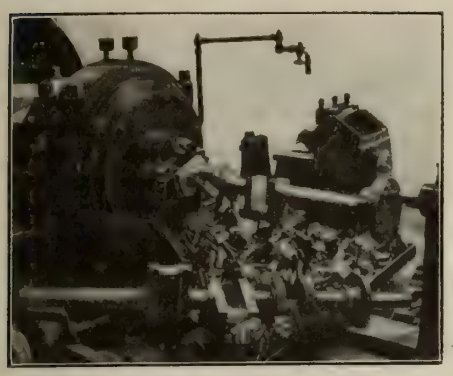

Fig. 2.—Crank Pin Turning Machine.

will be seen by Fig. 1, the headstocks are carried on a strong bed of box section, the interior of which is used as an oil-well for the cutting-tool lubricant; provision is made for returning the oil to the well after leaving the tools.

The headstock of the machine has a large hollow spindle carefully and accurately fitted; this spindle is actually a drum, large enough in internal diameter to accommodate the end of the crank-shaft, when fixed eccentrically to the extent of the required throw of the crank. On the face of this drum is mounted a special chuck, which fixes positively the exact throw of the crank; the crank-shaft itself is supported in the chuck close to the web, and at the other end, inside the spindle, by a special steady disc which can be moved to any point to suit the length of the crank. In addition to this the crank is further held by the web by means of clamping screws on the face of the chuck, thus eliminating all torsional vibration of the crank-shaft itself. The method will be best understood by reference to Figs. 1 and 2. The overhanging end of the crank-shaft is supported by means of a small following headstock, as shown in the illustrations.

The machine is provided with a specially long cross-slide, and on the front end of this is mounted a tool-holder, which carries the roughing tool. A second tool-holder, carrying the finishing tool, is mounted behind the crank-pin, so that the turning operation can be entirely removed without removing either the crank or the tools. In addition to the "necking" tool-holder a "crowning" rest is provided, fixed at the back of the cross-slide, for the purpose of topping or crowning the ends of the crank-webs. Both the cross-slide and the crowning rest have the necessary automatic feeds. For "crowning" the webs the crank is held in the same chuck as for necking; but to obtain its correct radial position for this operation, a second hole in provided in the chuck to receive the crank-shaft. A pump is fitted for feeding the lubricant to the cutting tools; this is driven from a separate constant-speed shaft on the gear-box, and a continuous and uniform supply of lubricant is secured at all speeds of the machine. Generally, the machine is of massive and strong design, and it is claimed that the work obtained by it is greatly superior to that produced by any existing method of machining crank-pins, both as regards quality of work and economy of labor.

Performance and Features.

In the table are given a few examples of cranks turned by the machine, and the time required for machining in all cases the time given covers the complete operation of fixing, machining, and taking the crank pin out of the machine when finished. At present the makers are listing one size of machine only with a barrel of 15 in. internal diameter; the maximum capacity is determined by adding the throw of the crank to half the diamater of the shaft. This sum must not exceed $7\frac{1}{8}$ in.

The chief features claimed for the machine are perfect alignment of crank-pin with the crank-shaft; pins finished round within a maximum limit of error of 0.0005 in.; perfect control of the finishing tool; and diameter of crank-pin accurately controlled by large graduated disc on the feed-screw. Once the disc is set, the correct diameter can be reproduced any number of times without actual gauging. There is reduction in labor charges. The machine is adaptable within the capacity of the barrel. Multiple-throw cranks can be machined as readily and expeditiously as cranks with a single throw.

Each machine is sent out complete with the fallowing parts:—Three "roughing" form tool-holders, three "finishing" form tool-holders, one "crowning" tool-holder and tool, one tool-grinding gauge, and all necessary spanners and accessories. A complete equipment of tools for machining one size of crank is supplied with each machine. This equipment consists of the following parts:—One crank-chuck, one crank-pin roughing tool, one crank-pin finishing-tool, one supporting dog, and one steady disc. The net weight is about four tons. L. Gardner & Sons, Barton Hall Engine Works, Patricroft, Manchester, are the makers.

HOW THE AIR BRAKE FIRST WAS USED.

The air-brake, writes Paul Latzke in Everybody's, was ushered into actual use in most dramatic fashion. The trial trip occurred in April, 1869. The train selected was the Steubenville accommodation running between Pittsburg and Steubenville, Ohio. When the train was going at full speed, suddenly, as he came around a sharp curve, the engineer saw a stalled wagon in the middle of the track dead ahead. With hand-brakes only, nothing could have prevented a terrible smash-up. The formal time for the trial of the air-brake had not come, but the brake was there, and in desperation, not believing for a moment that the thing could possibly avail, the engineer threw on the air. But it did avail. The observers in the rear were almost catapulted out of their seats by the shock of the sudden stop. But when they saw the engine fairly poking its nose into the wagon-bed, so narrow had been the margin between safety and disaster, they forgot all about their shock and stood in awed silence.

Lard oil is now the standard material for use in coating the cast iron molds used for casting brass for rolling. It should be of the best grade and free from mineral or vegetable oils. Fish oil was used for many years, but the smell is objectionable. It gives equally as good results, however, as the lard oil.

Gold is the most malleable metal, but the presence of as small an amount as 0.0003 per cent. of antimony will cause it to crack in rolling.

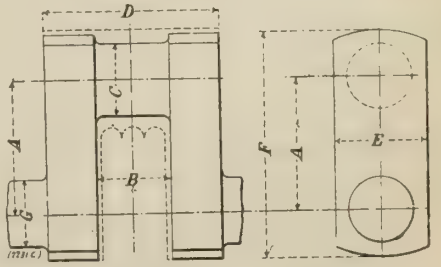

Table I.—*Time Taken to Turn Cranks, as in Figs. 3 and 4, on 15-In. Crank-Pin Machine.*

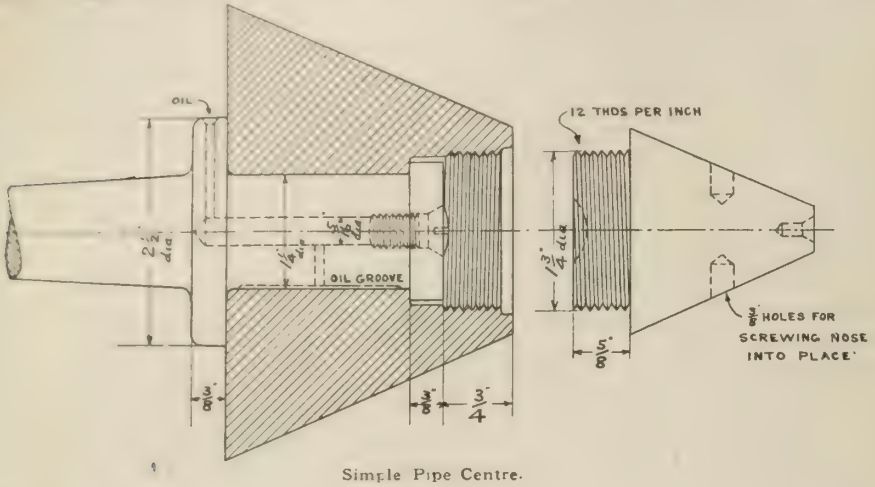
A.	B.	C.	D.	E.	F.	G.	Crowning Time in Minutes Each.	Necking Time in Minutes Each.	Total Time.
in. $5\frac{1}{4}$	in. 3	in. $2\frac{3}{8}$	in. 7	in. $3\frac{3}{4}$	in. $9\frac{1}{4}$	in. $2\frac{1}{8}$	8	25	33
$3\frac{1}{4}$	3	$2\frac{1}{2}$	7	$3\frac{1}{4}$	7	$2\frac{1}{2}$	7	22	29
$3\frac{1}{2}$	$2\frac{3}{4}$	2	$6\frac{1}{4}$	$2\frac{3}{4}$	$6\frac{1}{4}$	2	5	16	21

The times specified include setting and all other operations.
The dotted line shows the state of the crank-neck before turning, after the slab has been removed from between the webs by drilling and slotting in the usual way.
The machine is quite capable of turning the crank-neck from the solid forging, but it is found quicker first to remove the slab, instead of making chips of all the metal which has to be removed.

Fig. 3 and 4.—Crank Pin Turning Machine.



MACHINE SHOP METHODS AND DEVICES

Unique Ways of Doing Things in the Machine Shop. Readers' Opinions Concerning Shop Practice. Data for Machinists. Contributions paid for.

A SIMPLE PIPE CENTRE.

By J. C. M.

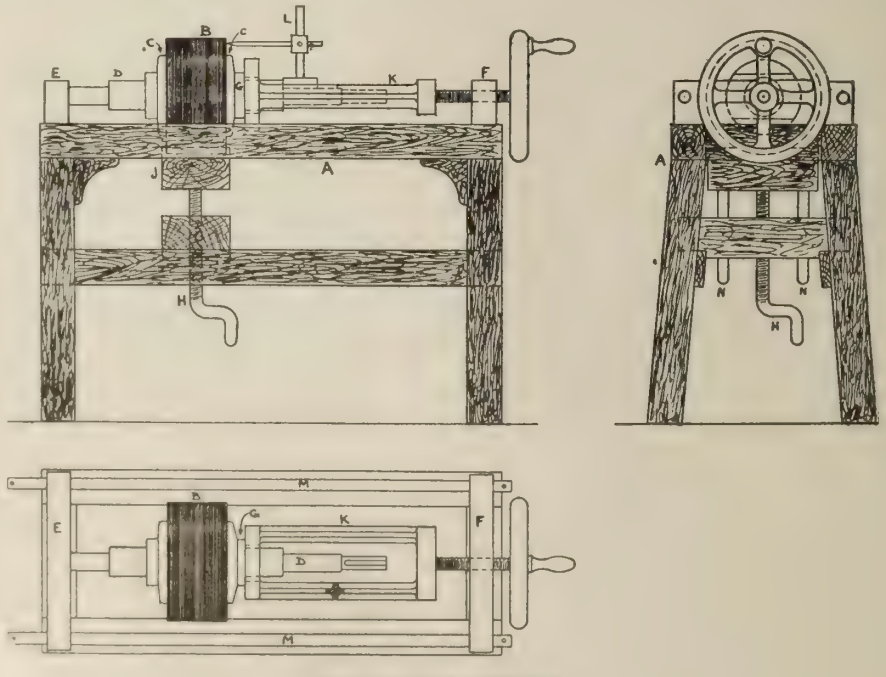
A pipe centre that has the advantage of not coming off the spindle when the pipe is removed, is shown in the attached cut, which is self-explanatory. The cone may be of any desired dimensions, and means for thorough lubrication of the spindle should be given careful attention.

Simple Pipe Centre.

The best way to make this centre is as follows:—First, form the male and female screw threads, then bore out the large part of the cone and make the spindle a tight driving fit. Screw on the nose, and turn cone to required size. Remove spindle and ease it until cone revolves readily without play. The spindle shank is made to fit into the lathe tail-stock spindle. The apparatus might be somewhat improved by having a vulcanized fibre washer between the cone and the spindle collar.

STACKING MOTOR ROTORS.

By A. Mitchell.



This press is used for pressing together the laminated iron plates that go to form the core of a motor armature, when they are placed on the shaft without a spider, and is of simple design, as may be seen from the cut.

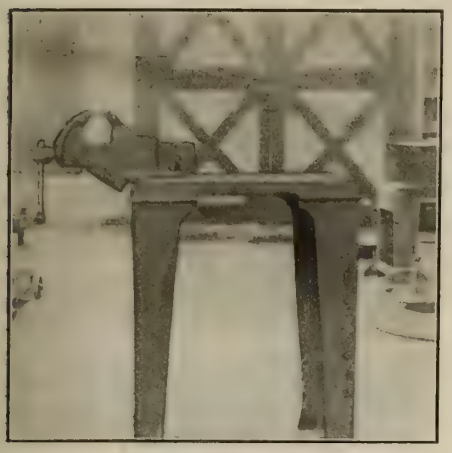
A is a wooden frame supporting the press, etc. B, the core or rotor consisting of iron disks about 0.1" thick. C C are cast iron flanges. D is the motor shaft. E is iron block against which the end of the shaft bears. F is a similar block forming a seat for the screw.

After the plates have been assembled between the flanges, a ring C is heated and placed in position. A yoke or collar K, which may be of aluminum for lightness, is then placed over the end of shaft, so that one end bears against the shrink ring A. The screw is brought to bear against the other end of the yoke and pressure applied until the rotor stands exactly central with the shaft journals. A surface gauge L placed against the end of the journals tells when this has been accomplished. When the shrink ring cools the rotor will be held firmly in position. It is important that it be exactly central, otherwise the pull to one side will cause excessive friction on one journal shoulder.

The rotor and shaft are supported by the wooden block J, which can be raised or lowered by the screw H, to suit the various roter diameters. The block J is guided vertically by two rods N working in holes in the lower bar which forms the nut for screw H.

MM are rods of cold rolled steel which take the thrust, and are about 1 inch diameter. Pins through the rods serve to adjust the length of the press to suit different lengths of motor shafts. The block J with its screw and nut can also be moved along the rail to any required position.

Rotor Stacking Apparatus.



INCREASED VISE FACILITIES.

By Don. A. Hampson.

Some time ago, a writer in Canadian Machinery spoke of the need of increased vise facilities, with particular reference to having same close to the work. There is no doubt as to the advantage of having vises accessible to machine and floor hands, and the portable tool is doing much toward this end. In our general machine department, the vises were bolted to the wall benches, making it necessary for floor, milling and planer men to walk from 20 to 50 feet every time they had to do a little filing or chipping (often several times an hour), this cut deeply into the day's production.

Reference to the photo shows the style of vise-stand we built to save this wasted time. The legs are a heavy stock casting as is also the top and these we combined as shown, putting in a stiffening rod at the bottom, and mounting

with a vise. Such an outfit takes care of anything a man can put between the vise jaws without its sliding around on the floor. When desired to move it, a shop truck is slipped under one leg. The top is planed, making a rough surface

Vise Stand

plate as well as a place to lay tools and work.

INTERESTING PIECE OF FORGING WORK.

By J. H. W.

Cast iron wheel centres for locomotives have never been looked upon favorably in European practice, and until the advent of steel castings, locomotive wheels were always forged of wrought iron. This was a job requiring much skill and care. The wheelsmiths were generally men who had grown up in the trade, consequently the reliability of the work they turned out and the smoothness of its finish, was remarkable.

The cut shows diagrammatically how the wheel was made. The spokes A were forged separately, while the rim was forged in small segments B, one such to each spoke, Fig. 1. These rim pieces were then welded to the spokes, as shown in Fig. 2. Another common practice was to forge the upper half of the spoke solid with the rim and afterwards weld on the other half spoke. The pieces shown in Fig. 2 were arranged in a circle, Figs 3 and 4, and clamped together.

One side of the wheel centre was then raised to a welding heat, and a thick disk or washer, C, Fig. 4, was similarly treated in another fire, the two being afterwards welded together, as were the spoke ends next the centre at the some time. The other side of the centre was treated in like fashion, on completion of which the wheel appeared as in Fig. 5. The next operation was to complete the rim by welding in wedge-shaped pieces at each gap, as shown in Fig. 6. An alternative method of doing this is illustrated in Fig. 7.

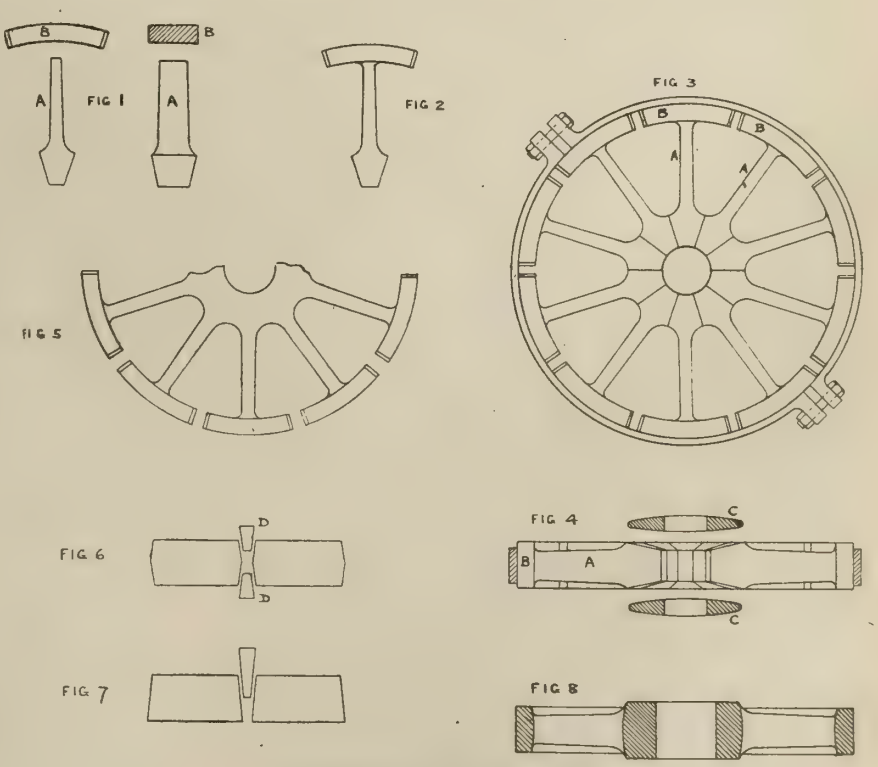
Fig. 8 shows a section of the completed wheel, ready to be faced, bored, turned and have the tire shrunk on.

WORKING IN THE DARK.

By J. W. I.

THE result of observation during a varied experience as machinist, leads me to say that in threading a left hand nut in the lathe, the operator never fails to adopt the method by which starting to cut the thread is performed from the inner or face plate end of the job. This I call working in the dark, as there is a much simpler and easier way of doing it.

If you have no reversing belt on the lathe, cross the cone belt, use a right hand instead of a left hand threading tool, then run your lathe backwards and start your cut from the front. By doing this, you can see how the tool is working and make calipering easy. This little kink may be helpful to journeyman and apprentice alike.



HIGH SPEED STEEL.

By J. H. W.

Before blindly deciding for high-speed steel, because fashionable, it is advisable in a small shop, that the superintendent go carefully into the question for himself, and see if he can really save money by adopting it. If his shop is equipped with modern machinery, he need have no hesitation in using it wherever possible. There are many shops, however, turning out good work to-day by means of machine tools which are distinctly old-fashioned. These old style machines were never built for heavy cuts, the cone pulleys and belting being too narrow to transmit the additional power required. In fact, all parts of the machine are generally found to be too light, to stand up to the strain imposed by modern high speed steel operation. Even were the line shafts speeded up and heavier belts put in, it will be found impossible to take heavier cuts than with carbon steel, owing to the excessive vibration of the machine.

All things considered then, it is highly improbable that more than 50 per cent. efficiency will be got out of high speed steel under these conditions, although it may be advantageously used for light rapid finishing cuts. The cost of reputable brands of high speed steel is from 2½ to 4 times that of ordinary crucible tool steel, therefore its purchase is not to be lightly undertaken unless it can be used at maximum efficiency. I do not wish for a moment to disparage its use in a shop fitted with modern machine tools, for under such conditions it has been shown over and over again to be well worth its extra cost.

Modern theory points to the advisability of the old-fashioned shop scrapping its machinery as rapidly as possible, and installing thoroughly up-to-date machine tools. This course generally pays better than attempting to stiffen and speed up tools that were never designed for the work now demanded of them.

An Interesting Piece of Forging Work.

Annual Outing of the Central Railway Club

By J. H. Williams

Being a brief account of how busy men spent a profitable and healthful day, forgetting for the time being, and wisely so, the stress and pressure of their week day callings. Such outings are a fitting climax to the work of the club during the winter, and do much towards arousing enthusiasm for future sessions.

THE fourth annual outing of the Central Railway and Engineering Club of Canada, took place on Saturday, June 17th About 250 members left Toronto at 9 a.m. by special train for Beaverton Beach, on Lake Simcoe. During the journey out and return, the energetic members of the committee, arranged as chefs in spotless white, dispensed various forms of refreshment, as well as some excellent smokes,—in fact the quality of the stogies was the subject of much favorable comment, and "Canadian Machinery" enjoyed them as much as any.

Doings at Beaverton.

Blea's Band was in attendance, and under the conductorship of genial Bandmaster H. G. Fletcher, headed the procession from Beaverton station to the hotel, where the camera man promptly went through his usual stunt.

The first event on the programme of sports was shortly afterwards brought off. This was described as a grand scramble to the dining hall; and strange to say, every member present entered. When the demands of the inner man had been amply satisfied a general move was made to the sports field, where the band was discovered parading in fantastic costume,—a very tall Highlander in a very short kilt being the most conspicuous figure; although all were a success.

Event No. 2, was soon called in the stentorian and megaphonic tones of Announcer E. A. Wilkinson. This was a grand five-innings baseball match between the Mechanics and the Pedlars, for a silver challenge cup. The game, which ended in a win for the Mechanics (6—5), created great excitement, and the frequent advice tendered to "Mike," showed that A W Carmichael was occupying a large share of the fans attention.

The third event.—Avoirdupois Championship, was very keenly contested. None were eligible unless measuring at least 40 5-64 inches around the "lower chest"—no blowing out during measurement permitted. One yard handicap allowed for every inch over the minimum permissible size. The distance was 100 yards and the race was won in great style by James Wright, with A. W. Carmichael a good second. The official time was a world's record?

The fourth event provided lots of fun. This was a three-legged race or triple expansion championship,—distance 100 yards. The wise ones traveled with a half open throttle; but one couple started off under a full head of steam, making great speed until nearing the mark, when their connecting rod buckled and wrecked the whole engine. The winners were T. Jeffries and R. S. Mabee. Time 14 secs.

Fifth Event,—The Tobacco Trust Competition, 100 yards.

Each competitor was provided with a clay pipe, tobacco and five matches. On the pistol shot he had to fill his pipe and light it before crossing the seven-yard mark and have it going at the finish. Bad firing caused the downfall of many of the contestants, and the race was won easily by G. Adams, the second and third being Geo. Cook and W. G. Adams. The two latter arrived at the tape the first time with their pipes out and had to return to the seven-yard mark to light up again.

Sixth event.—The Patriarchs' Rejuvenation. A "wait" for age event. 100 yards dash.

This was a handicap for men of 55 years or over,—one yard handicap for each year over age. The committee announced that in case of any dispute as to age, a qualified veterinary surgeon was on hand to settle the matter by an examination of the teeth. Amid the plaudits of his supporters, J. Kelly came in first, with S. Best, second best.

Seventh event.—Standing Broad Jump won by F. Scott, with a jump of 8 feet 9½ inches; J. Sharpe being second with 8 feet 6½ inches.

Eight event.—Relay race, once around the field. 1st, T. Cairns; 2nd, Purvis.

Ninth event.—100 yards dash open to all. This race caused lots of excitement, and was won by B. A. Dillon with W. G. Reid second and R. Polson third.

Tenth event.—Open walking match, once around the field. 1st, J. Lawless; 2nd, J. Smith.

This was a good race, inches only separating the men at the finish.

The sports wound up with a grand tug of war, Mechanics versus Pedlars; best of three pulls. The tension was terrific, both on the rope and amongst the spectators; the Mechanics finally being awarded the victory after a prolonged struggle.

President Baldwin, Vice-Presidents Bannon and Taylor, and the other members of the executive, worked hard all day, and it was largely due to their efforts, that everything passed off so successfully.

Presentation of Prizes.

At the end of the afternoon, handsome prizes were handed to the lucky winners by President Baldwin. They consisted of cut glass decanters, brass jardineres, safety razors, hammered brass trays, fountain pens, calabash and briar pipes, cigars, etc., etc.

The members of the winning baseball team each received a handsome umbrella, and the manager was entrusted with the care of the silver challenge cup for the next twelve months; it having to be won three years in succession before coming the property of the winning team.

Several members of the club spent the afternoon on the lake fishing, and returned with the usual yarns of the big ones they lost.

After a substantial supper at the hotel the band headed the return trek to the train, where the two-hour run back to Toronto was passed away in song and mirth; bringing to a close a thoroughly successful and enjoyable day.

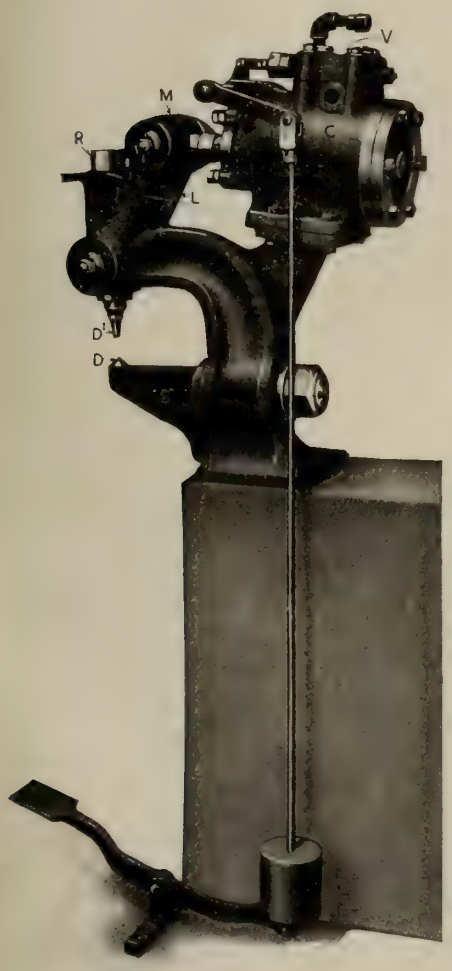
MONTREAL TECHNICAL SCHOOL.

One of our representatives had the good fortune recently to be present at the trial of the large blast-furnace which has been installed in the foundry of the new Technical School, Montreal. At the conclusion of the trial, Mr. Macheras, the energetic principal of the school, made a tablet casting bearing the following inscription :—"January 7, 1911.—This tablet is the first piece of iron cast in the Montreal Technical School. G. DeSerres, President, H. J. White, Secretary-Treasurer, A. Macheras, Principal."

The foundry apparatus was made and installed by F. Hyde & Co., Montreal.

The interesting ceremony began at half-past two o'clock, at which time the furnace was lighted and put in operation. Less than an hour afterwards, the mould was opened, and after cooling, the tablet was completed and placed before those present for inspection.

The blast furnace is operated by compressed air and is of latest design. The first cast was highly creditable to the fitm of F. Hyde & Co., and particularly to their representative, Mr. Cote, who assisted throughout the trial.



DEVELOPMENTS IN MACHINERY

A Record of New and Improved Machinery Tending Towards Higher Quality and Economical Production in the Machine Shop, Blacksmith Shop or Planing Mill.

ALLEN ADJUSTABLE STAKE RIVETER.

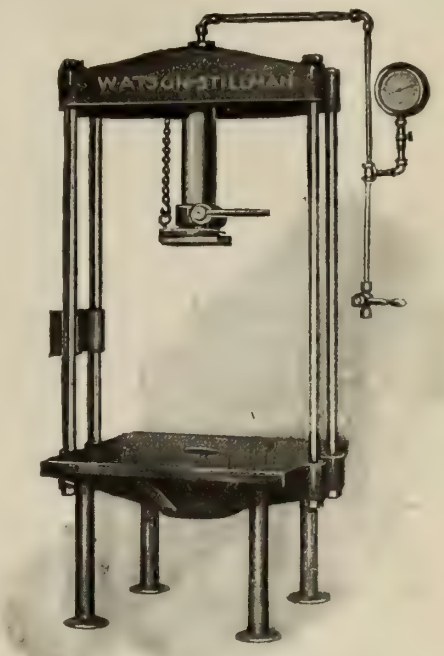
THE engraving shows a riveter of unique design and construction, recently built by the John F. Allen Co.,370 Gerard Ave., New York City, for sheet metal work. It is one of the smallest riveting machines built by them, having 7½ inch reach, variable gap and 5½ inch cylinder.

While embodying all those features which have contributed so largely to the

Allen Adjustable Stake Riveter.

success of Allen riveters as a type, it possesses, in addition, many original features of especial value for the work intended. It is designed for sheet metal work where the rivets used run from 1-16 to ¼ inch diameter, and are driven cold. The stake "S" is easily removable in order to permit of other stakes, suitable to the work in hand being used. This materially increases the range of work that can be handled, and will be found a great convenience, as stakes can be made of any shape or size at comparatively small cost to suit the most unusual and difficult jobs.

The machine can be operated by foot pedal, as shown in the illustration, or by hand lever, as desired. The work to be riveted is placed with the head of the rivet resting on the holding-on die "D," so as to bring the end of the rivet in line with the upper die "D-1," which usually stands about ½ inch above the top of the rivet. By pressing the foot on the treadle, air of from 60 to 100 pound pressure is admitted to cylinder "C." This causes the piston to move forward, and the side links "L" and middle links "M" to assume a position parallel to the axis of ram "R." The ram carrying the upper adjusting die "D-1" is thereby forced down upon the end of the rivet, forming a head with one stroke. By relieving the foot pressure on the treadle, the slide valve in valve chest "V" reverses the motion of the piston, and this returns ram "R" to its original position ready for the next rivet.

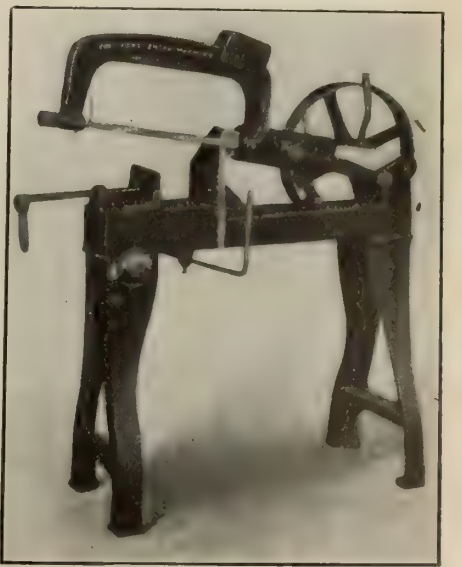


The number of rivets that can be driven within a given time is entirely dependent upon the operator, as the time consumed by the machine in driving the rivet is practically negligible. The amount of air consumed per rivet does not exceed 1-5 of a cubic foot. The machine is noiseless in its operation, and can be placed in any convenient location in the shop without interfering with other equipment. If preferred it can be operated by steam.

HANDY HYDRAULIC PRESS.

THE small hydraulic press, which we illustrate, was designed by the Watson-Stillman Co, of New York, for laboratory work and for crushing specimens of building material, but has proven most useful in machine shops, where small parts are press fitted, and where high pressure needs be brought to bear on small articles, for bending, straightening or flattening. It can be applied to endless odd jobs about any shop.

Convenient size premits this press to be mounted on a light truck and hauled from place to place, the operation being quick and easy Rapid movement of the ram is facilitated by the lever and connecting links shown at the left. The handle at the right, on the extension lever socket, will operate the pump easily where only light pressures are required, and by applying the extension lever there may be developed a pressure of 30 tons. The platen area is 8 in. square; the platens are 8 in. apart at maximum opening, and the ram movement is 4 in. The base is 12 in. by 16 in., and the height overall is 27 in. The main cylinder is a steel forging, machined to fit perfectly into the reservoir, and the pump cylinder is of bronze.



The press is designed to withstand severe service, and is ideal for small work requiring high pressures.

Handy Hydraulic Press.

A NEW TYPE OF POWER HACK SAW.

The hack saw illustrated and built by the Ford, Smith Co., will cut all classes of material up to 5 inches sectional area.

Ford Smith Hack Saw.

The saw frame and guide are cast in one piece, and have a long bearing on the guide bar. This guide bar is a special feature of the machine, being of rectangular section, instead of the round guide found on a number of machines. One end of the guide bar swings on the same centre as the driving shaft; the other end being guided on an extension of the back jaw of the vise, ensuring a true, square cut. The gong is another useful feature, ringing loudly when the piece is cut off, and ensuring attention on the part of the attendant.

The machine weight is 160 pounds, well distributed. This, together with the long connecting rod and rectangular form of guide bar, enables it to be run to its full capacity without vibration, a feature adding materially to the life of the saws.

PIPE-BENDING MACHINE.

The text and illustrations, figs. 1 and 2, are descriptive of an efficient type of machine for bending pipes and tubes, and is suitable and convenient for steamfitters and others handling these wares. It has all the advantages of the more expensive machines made for a like purpose, and in its largest size, is compact and light enough to be carried in a workman's bag. The machine consists of a number of grooves whereby varying sizes of tube can be instantly bent without change of parts being necessary, and one bend may follow another in any direction quite closely to the last one. Simplicity of construction is another recommendation, as any strong youth can understand and operate it. Two inch piping can be bent with ease to a variety of angle, and will lose hardly any of its contour in the process. The complete range manufactured, will deal with any size pipe from $\frac{1}{8}$ to 4 inches O.D. The smallest has a capacity of $\frac{3}{4}$ inch and weighs only 24 lbs., while the largest has a capacity of from 1 to 4 inches. Sizes 1 and 4 constitute a complete installation for dealing with every grade between $\frac{1}{8}$ and 4 inches, and the three smallest sizes, the largest of which bends up to 2 inches, may be fixed to a strong bench or table, or carried on a pipe vise. The "FORTUNA," being the trade name by which the machine is known, is made by the Fortuna Machine Co., Leicester, England; the Canadian Agents being Francis Hankin and Co., Montreal.

HEAVY WET TOOL GRINDER.

The Ford-Smith Machine Co., Hamilton, Ont., have recently put on the market a new type of heavy wet tool-grinder which has some novel features. In a machine shop, large outputs and accurate work depend to a great extent upon the tools being correctly ground. With a powerful, well-balanced wheel of the proper grain and grade and running at the right speed, with an easily regulated water supply, the operator can keep the tools in the best shape, with a minimum of time and trouble.

Fig. 1 shows the general appearance of the machine. The body cast in one piece, is exceptionaly stiff, sits solidly on the floor, and forms a tank which extends to within about fifteen inches of the bottom. The door shown in front gives access for cleaning out the tank after it has been emptied by means of the drain cock.

One of the most important features of a grinder is the spindle, and in this machine it is of liberal proportions and runs in long bearings lubricated by self-oiling rings.

To allow the wheel to be run at an approximately constant peripheral speed as it wears down, a two step cone pulley is provided. This may be replaced by a fast and loose pulley if desired, (the necessary belt shifting gear being attached to the machine) which can then be driven direct from a main line shaft.

The system of water supply is novel. It can be easily regulated by the hand wheel in front to give any desired delivery from a light flow to a heavy flood, pumps and pipings being entirely dispensed with. The wheel runs in a hinged segmental trough, which can be raised or lowered by the rod and hand-wheel at right hand side of the machine, thus regulating to a nicety, the amount the wheel dips into the water. The overflow and splash run back into the main body tank, from which it may be drawn off and returned to the trough at intervals, such as when putting in a new wheel. The hood is brought well forward of the centre line, and has side flanges to prevent water being splashed backward. A swivel cap is also provided to ensure water being delivered on the tool as the wheel wears.

The tool rest is designed so that all the usual tools may be easily manipulated, and is shaped at the back to allow a deep clearance to be ground on long tools, a feature which is not always given sufficient attention by designers. Another special feature of the machine is the removable tray. For or-

Fig. 1—Fortuna Pipe Bending Machine.

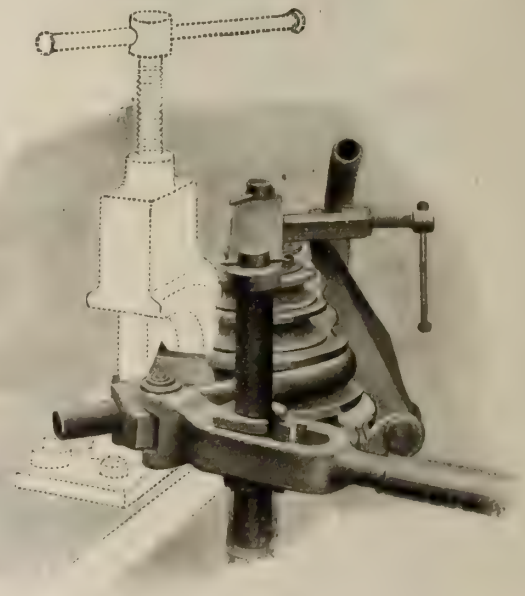


Fig. 2.—Fortuna Pipe Bend ng Machine.

dinary shop-tool-grinding, the tray remains on, as shown in the cuts, in which position all splashing is confined inside the pan, thereby keeping the operator dry. For extra long tools, however, the high edge of the tray would not allow of the necessary clearance being ground, so it is simply lifted off, being replaced when the tool is finished.

Fig. 1.—Heavy Wet Tool Grinder.

The machine presents a neat appearance, is substantially and heavily built, and furnished with a countershaft having self-oiling bearings and double sided hangers. Fig. 2 shows the wheel trueing device.

A NEW ENGINE LATHE.

A new design of high duty engine lathe has been brought out by the American Tool Works Co., Cincinnati, Ohio. It is made in two sizes, 36 and 30 inch, and embodies several interesting features. Abundance of power is secured; more than sufficient to allow the use of the most improved high speed steels available. The general design of the lathe is correspondingly massive, ensuring rigidity and absence of chatter.

The lathe is made with five different types of headstock, as will be presently described. Fig. 1 shows the 36-inch lathe equipped with the patented geared head and motor drive. A constant speed motor, either A.C. or D.C., is located on the top of this geared head and connected to the main driving shaft by three gears. The motor is under constant control by means of the controller hand-wheel, conveniently located at the right hand end of the carriage.

The patented geared head gives twelve spindle speeds, ranging from 6 to 257 r.pm. The head is of the compound back-geared type and is of massive and rigid construction. Only 14 gears are used to give the 12 spindle speeds and the changes are made by hand wheels and levers on the head front. The gears are designed to allow of comparatively high motor speed—1,000 to 1,200 r.p.m.—thus keeping down the size and first cost of motor. A sensitive friction clutch is provided on the driving gear for starting, stopping or slightly moving the gears in the head, in order to facilitate making speed changes without shock to the parts or interfering with the motor speed.

The spindle is of high-carbon, hammered steel, and has a 2 9-16-inch hole throughout its length, the spindle bearings being of phosphor bronze and fitted with sight-feed oilers.

An entirely new feature of these lathes is the quick change gear mechanism, which has been developed to a high pitch of excellence. All steel gears are used, and the mechanism provides a range of changes for feed or screw cutting which is practically unlimited. The index plate is situated on the feed box directly over the sliding tumbler, and clearly shows how to obtain each thread and feed. The feed box consists of a gear box on the front of the bed, with two levers and a steel sliding tumbler, the latter working in conjunction with a cone of eight steel gears. The cone of

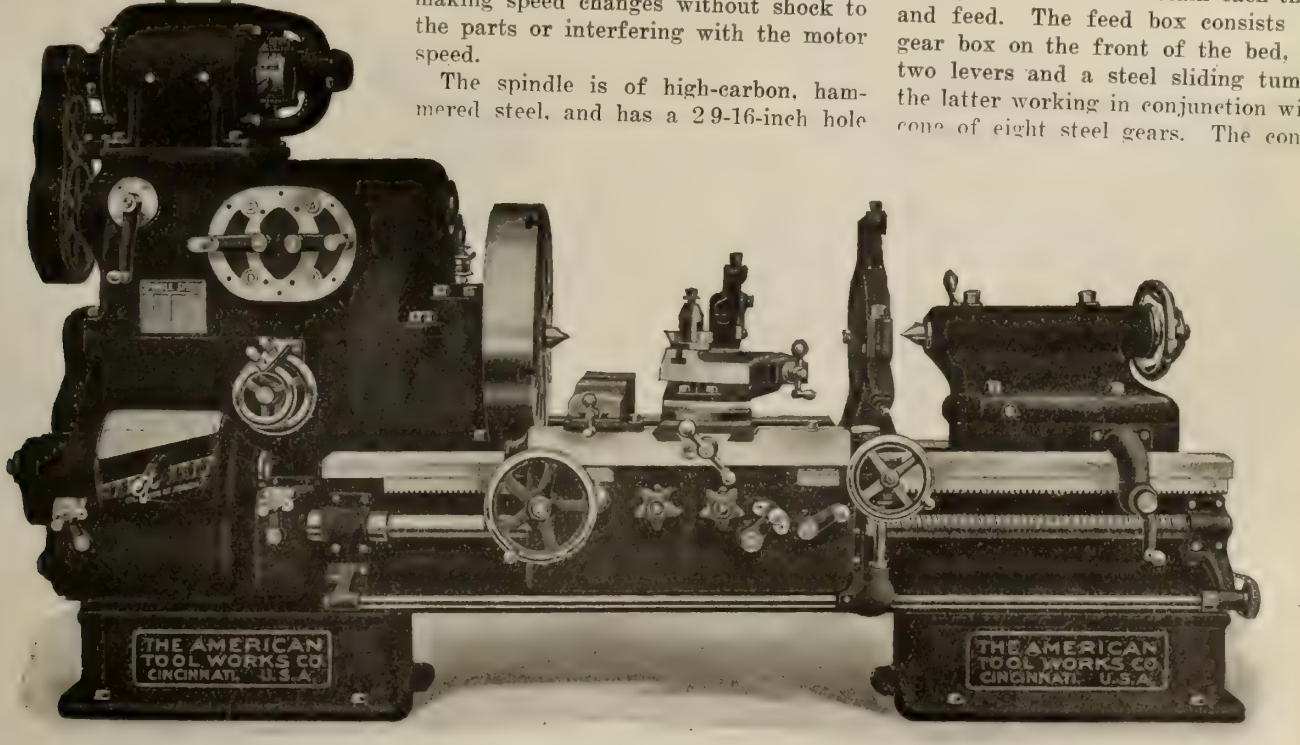

Fig. 1

Fig. 2.—Heavy Wet Tool Grinder with Trueing Device.

gears and also the tumbler gear are cut by Brown & Sharpe 20-degree involute cutters, which produce a tooth pointed at the top and exceptionally wide at the base. This form of tooth is unusually strong and permits of instant engagement while running, without the tumbler gear riding on top of the cone gear before dropping into place.

The carriage is of heavy construction, especially in the bridge. It has a full continuous bearing of 44 inches on the V bed. As may be seen from the cut, the apron extends the full length of the carriage, and is double, so that all shafts passing through it have a double bearing. Both longitudinal and cross feeds are reversed through a lever from the front of the apron, and not at the headstock, as on most lathes. This is a great convenience on long tools, where the operator is some distance from the headstock. All gears and pinions in the apron are steel, cut from the solid, and can be conveniently lubricated from the front.

The rack pinion can be disengaged from the rack when screw-cutting is in progress, and means are provided to make it impossible to simultaneously engage the feeding and screw-cutting mechanism.

As before mentioned, the lathes are built with five types of headstock. Fig. 2 shows the patent geared head arranged for belt drive; the head is identical with that shown in Fig. 1. A flat surface is provided on the top of the gear box so that it is an easy matter to change over to motor drive at any time after the installation of the lathe, if desired. All that is required is to instal a motor on the flat surface provided and connect the armature and main driving shaft by three gears. It is a simple matter to substitute a gear for the pulley on the driving shaft.

Figs. 3, 4 and 5 show other forms of belt-driven headstocks. Fig. 3 is a powerful triple-geared head, having a 4-step cone pulley, giving twelve spindle speeds. The steps of the cone pulley are of large diameter and take a 5¼-inch belt; a large area of belt contact being provided. The gear ratios are extra high, so that ample power is ensured for any work within the capacity of the machine.

Fig. 4 shows a double back-geared headstock. This gives nine spindle speeds, 3 direct, 3 reduced, and 3 double-reduced.

Fig. 5 shows a head designed for medium class work. This is a single back-geared head with a 4-step cone pulley, giving eight spindle speeds.

The lathes have a standard length of bed of 10 feet, but any length will be made to order, advancing by 2-feet lengths.

The 10-foot bed takes 4 feet 3 inches between centres when the patented geared head is fitted, and 3 feet 9 inches when a cone head is used.

Co-operation Between Central Station and Manufacturer *

By Chas. F. Scott **

Showing That an Exchange of Views and Opinions Results Beneficially to Both Parties, and in Addition Affects Favorably the Community as Ultimate Consumer. The Writer is a Representative of a Large and Well-Known Electrical Equipment Manufacturing Concern, and His Ideas Formulated in this Paper, Voice the Expressed Desire We Believe of Reputable Makers of Machinery, Electrical and Otherwise, While the Subject Chosen Deals More Directly With the Relationship That Should Exist Between the Manufacturer and Operator in One Section of the Whole Wide Field of Engineering, We are Certain That Similar Co-operation in Other Spheres Would Tend Likewise to Improved Quality of Results and Decreased Trouble in Attaining Them.

CO-OPERATION between the central station and the manufacturer of apparatus will be treated for convenience under three heads ; first, "Engineering," which will deal with the apparatus by which the central station produces and distributes its current ; second, "Commercial Engineering," which will treat of the apparatus (such as motors, lamps, heating appliances), and the methods for extending the use of central station service ; third, "Commercial," which will deal in a more general way with the common commercial interests and prosperity of the central station and the manufacturer.

I.—Engineering.

Good apparatus well operated is the engineering basis upon which the whole central station business rests. It is useless to expect good service from badly designed or badly built apparatus in which central station operators have no confidence. How can the central station co-operate with the manufacturer to secure better apparatus ?

Standard apparatus should be purchased if it will meet the requirements. Modern manufacturing is based on the principle of duplication, of making things in quantity. Designs are carefully prepared and are modified as experience directs, so that much of the standard apparatus of to-day is the outcome of years of evolution in which the best thought of the designer, the best skill of the factory and the results of experience are combined. Patterns, dies, tools and the experience of the workmen all are available for the making of a standard product in less time and at less cost than a special or new one which has not had the test of service. Hence, whatever the individual central station or central stations together, can do toward the standardization of voltages, frequency, and the acceptance of standard types and sizes of generators and auxiliary apparatus, will not only assist the manufacturer, but will in the long run, bring to the central station better and cheaper equipment.

Conference with the manufacturer before deciding upon a definite type or size of generating unit or other apparatus may be helpful in determining what standard apparatus is available to most nearly meet the requirements. Substantially the same or sometimes even better results, can be secured by such a conference, as are attainable with special apparatus, in addition to a gain in first cost, in time of delivery, and in securing machines which are of standard type. The central station is thus assured of getting the apparatus most suitable for its service, by securing the advice of the engineering department of the manufacturer which is necessarily in touch with the new and changing conditions, and with the operating requirements of other stations. The wisdom of such a conference is obvious, yet it is not uncommon for rigid specifications to be presented without conference and without provision for alternative propositions.

Electric Practice Development.

On the other hand electric practice is continually developing. We must continually improve and progress. New conditions arise. To improve his apparatus, the designer should know just what it must do. He may surmise the conditions, and he may make laboratory tests, but these may not be the actual requirements and conditions of service. He needs the experience which the central station operator possesses. Lightning arresters for example, designed according to theoretical principles and tested in a laboratory were liable to some startling surprises when installed on operating circuits. The development of the present arresters has come about largely through the visits of the designing engineers to the power houses and circuits of the operating companies, and through the assistance rendered by the operating engineers. Likewise regulators, switches, circuit breakers and instruments are the outcome both of the laboratory and experience in actual service. Now the experience of the central station operator can greatly assist the manufacturer. To be effective, there must be freedom and frankness—not mystery and secrecy. If something is not satisfactory, if there is some weak point in the apparatus, if there is some new condition which is not met, little is gained by saying that the whole thing is a failure, while much may be gained by definite, intelligent information.

Conditions are rapidly changing in central station designs, and substantial engineering progress requires that the skill of the manufacturer and the experience of the operator be combined. Perfect apparatus we can hardly hope for, but we shall come more nearly to attaining it, as the engineers of central stations and of manufacturers, recognizing that they have common problems, set about to solve them in a businesslike way to which each contributes his part.

II.—Commercial Engineering.

The growth of the off-peak load and of the power business is the most striking feature in central station activity at the present time. Motors are replacing engines in industrial plants ; they are finding new fields in domestic and commercial use to an extent not thought possible a few years ago.

This development is the outcome of a new type of engineering study and commercial activity. The application of electric power is first of all an engineering problem. A motor must be adapted in speed and power, and in mechanical connection, to the work which it is to do ; but beyond these simple problems, is the general problem of using to best advantage the power which the motor develops. It is the superior service which the motor gives, the convenience with which it can be operated, the better speed adjustment, the increased quantity or the improved quality of the output of the machine it drives, the simplicity of motor drive as compared with engines and shafting and belts, and the independence of one tool or one department from others when driven by separate motors —these and a score of other factors are the indirect advantages which often become the really important things to be gained in using electric power.

*Paper read at the 25th Annual Convention of the Canadian Electrical Association, Niagara Falls, Ont., June, 1911.

**The Westinghouse Electric and Manufacturing Co.

Hence it is the specific, the particular, and the definite adaptation of electrical appliances which bring results. The knowledge of how to accomplish these results comes through careful investigation and experience. This is often beyond the scope of the individual central station company, but it is something which must be undertaken by the manufacturing company, as it must know what are the exact conditions in order that it may design its apparatus so as to meet them effectively. For example, if a motor is to operate a certain tool, the designer must know the maximum power, the average power and the need for speed adjustment and variation. He must know these things in their relation to each particular machine or industry. He naturally acquires an intimate knowledge with the power requirements and the power consumption in actual practice in many places. He also determines the advantages and disadvantages which result in actual experience under many different conditions. It is just this kind of knowledge and experience which is essential to an intelligent and successful building up of the motor business.

Education of the Consumer.

The prospective user of electric power is often unfamiliar with the apparatus and the various engineering features involved in its application and operation, and he is ignorant or unconvinced of the advantages which will result from its commercial introduction. Hence it is, that the large power loads of progressive central stations have been the result of a systematic educational campaign among prospective customers. This is a field in which manufacturing company and central station can work together. The information and data which the progressive manufacturing company necessarily acquires in order to design its apparatus to meet the requirements of actual service are the precise data which the central station needs in order to understand and effectively present the situation to the power users who should serve.

Electricity applied either through motors, lamps or heating devices is usually an auxiliary factor. The cost of electric power is a small part of the total cost, and yet it may contribute very largely to successful operation. For example, the cost of power in most industries is only three or four per cent of the total cost of the product, and the cost of lighting is less than one per cent. Hence it follows obviously that if greater or better service can be obtained from both or motors by an increase or an improvement of the power or light, then considerably greater expense for light or power is amply justified. This may be illustrated by an example. Assume as a convenient basis that the cost to the purchaser for a 5 h.p. motor is $100.00. Assume further that the annual charge for depreciation, interest and repairs is $20.00 per year, or say $.07 per day. In the daily cost of production, therefore the first cost of the motor appears as 0.07. The power taken by the average 5 h.p. motor is say 2 k.w. (corresponding to a load factor of 40 per cent.); hence, the power for the 10-hour day will be 20 k.w.-hours and, if the rate is say, $.025 per k.w.-hour, the cost will be $.50 per day.

If the motor drives a line shaft supplying power to five workmen at $2.00 per day, their wages will amount to $10.00 per day. The various overhead charges in the operation of machine tools is about one and one-half times the operators' pay. (See "Notes on the Cost of Operating Machine Tools," A. G. Popcke, Electric Journal, December, 1909). This gives the overhead charge as one and one-half times the wages, or $15.00 per day.

The various items assumed in the total cost of production, with this 5 h.p. motor, in the present typical case, are as follows:—

Cost of motor per day	$ .07
Cost of power per day	.50
Cost of wages per day	10.00
Cost of overhead per day	15.00
Total cost per day	25.57
Total cost per hour	2.56
Total cost for twelve minutes	.50
Total cost for one minute	.04

Analysis.

The cost of power is $0.50 in a total of $25.57 per day, or only 2 per cent. of the total. Suppose that it be possible by using more power to slightly increase the output, note what will result. If the power used were increased one-tenth, making $0.55 instead of $0.50 per day, and this increases the output by say 5 per cent., then the production will be increased in value by 5 per cent. of $25.57, or a little more than $1.25. Hence, $0.05 more spent for power would result in a net gain of $1.20 under these conditions, or twenty-four times the cost of the additional power. These figures may be put in the following form:

Assumed gain in production	$1.25
Assumed additional cost of power	.05
Net gain	$1.20

Expressed in another way, the cost of power per day is $0.50, which is equal to the total cost for 12 minutes; i.e., one can afford to pay twice as much for power if he could thereby gain more than 12 minutes per day. Hence, the problem is not to save power, but to use power effectively. The cost of power is so small an item in the present example that it can be even doubled if a gain in rate of production of more than 2 per cent can be secured thereby.

The cost of the motor is equivalent to $0.07 per day, or approximately one-quarter of one per cent. of the total cost. Obviously, if some other motor equipment would give even 1 per cent. greater output, the value of which would be $0.25 per day, it would be economical to install it, even though costing twice as much.

Expressed in still another way, the cost of the motor per day ($0.07) is less than the total cost for two minutes ($0.08). Hence, if one motor equipment will save more than two minutes per day over another one, its purchase is justifiable even if the price were twice as great. If therefore, one motor outfit be more conveniently operated, if starting or stopping requires less time, if there is less interruption due to poor insulation or hot bearings or controller contacts, which amounts on the average, to even one or two minutes a day, or to one hour a month, then it is well worth while to purchase the better outfit even at a very considerably increased cost.

The same line of argument may be used in comparing group drive with individual drive. It is well known that the power consumption is in general, less with individual drive than it is with group drive, but that the first cost of several small motors is more than the first cost of one large one. If however, the cost of motors is a small part of the total cost (in the above example it represents less than 1 per cent. of the total cost of production), then it will be economical to use the individual drive, provided that even a few per cent. increase in output can be secured. Often the elimination of delays due to belt repair, shafting troubles and the like will alone much more than make up for a very considerable increase in the first cost of motor equipment.

In view of the foregoing analysis, it is poor economy to try to economize by reducing the amount of power used, provided more power can make even a slight increase in the output. Further, it is poor economy to try to economize in purchasing motor equipment, because any appreciable gain in production will much more than offset the increased cost of the best possible equipment. The figures in the foregoing example are assumed, but the actual figures applying to any practical case will usually lead to similar conclusions.

Lighting and Heating.

In the departments of lighting and heating, there is a similar situation. As the applications of electricity become more specialized, they are being handled in a scientific way. In incandescent lighting for example, the advent of the tungsten filament lamp is coincident with the rapid progress of the science of illuminating engineering. Formerly an incandescent lamp was placed wherever

there would ordinarily have been a gas jet. Now, correct lighting is laid out by illuminating engineers. The comparative newness of this work is illustrated by the appendix to the lecture on "Illumination Calculations," delivered in the series of lectures on Illuminating Engineering at the Johns Hopkins University last Fall. Following the lecture is a Bibliography of Illumination Computations in which there are references to 36 different books or articles. Two of these are without date, a few appeared in 1906, and all the rest have a later date. In other words, the literature on Illumination Calculation is just about as old as the tungsten lamp.

The manufacturers of lamps and of reflectors have made a scientific study and practical investigation as to the best ways of using their products, and are ready to aid the central station in specifying good illumination. This is bringing about a new era in electric lighting. Ten years ago, there was the small carbon incandescent lamp and the carbon arc lamp. These had existed with little change for twenty years, but within the past decade have come new lamps of various types, taking less than half the energy for the production of the same light, having a wide range in candlepower and leading to a scientific treatment giving practical results which were before unattainable. Simple as these things are, they are not understood by the general public, and the application of what is now available can come only through the progressive commercial presentation of the engineering principles which are now established.

The purpose of lighting offices and factories is to enable the workers to do their work. Good lighting promotes speed and accuracy by enabling things to be seen better. It places the workers in more agreeable and cheerful surroundings, and removes the cause of eyestrain and headache. Now, the total cost of lighting is trivial compared with wages, and the difference in cost between good light and bad light is often less than 1 per cent. of the cost of the wages. In other words, if an amount equal to 1 per cent. of the wages be used for improving the lighting, a gain of many times this amount can be secured in the quantity and quality of the work produced.

Likewise in heating appliances, the field is new, the conditions of application are varied, the fundamental facts and the resulting advantages are not understood by the general public, and there is again necessary an active commercial effort along sound engineering lines in order to develop this field. Here again the designing engineer and the manufacturer who has made a study of the conditions under which this apparatus can be applied, is ready to lend most valuable assistance to the central station in the extension of the work.

In cases where the first cost of a motor is small compared with the cost of the power that it consumes, and where the cost of heating or other current-consuming devices is small compared with the value of the current which they use, the central station has the opportunity of furnishing upon favorable terms or even free, the motors or heating apparatus with the expectation that the income from the current used will pay a handsome profit. With the 5 h.p. motor which has been cited as an example, the cost of the motor is 7c per day, whereas the value of the current it uses is $0.50 per day, or seven times as much. A flat-iron or luminous heater soon consumes current far beyond its original cost. Even the economical tungsten lamp of average life consumes current equal to many times its first cost. The first cost of carbon lamps is so low, compared with the current they consume, that the free renewal of lamps is a common practice. The ordinary person however, probably objects more to pay $0.20 or $0.25 for a lamp than he does to paying $3.00 or $4.00 for the current it may consume. Likewise, a man may hesitate to pay $100.00 for a motor although he may be perfectly satisfied to pay $200.00 per year for the current it uses. Hence, a study of the relations between first cost and power cost will often open the way by which the central station can cultivate the habit of using electricity by a generous policy in the furnishing of apparatus.

CANADIAN MACHINERY.

This mid-summer number of Canadian Machinery is brimful of live topics engaging the attention of the engineering profession in all its grades and varieties. Simplicity of treatment will be found to pervade the subjects dealt with. By becoming a subscriber you are assured of being kept up-to-date in your practice, as well as being assured of intimate touch with the sayings and doings of men in the forefront of mechanical progress.

We are all apt to take too narrow a view ; we fail to see that the really important thing is not the saving of a few cents in doing a thing by the old way, but in the large economies which come from new methods which electricity makes possible. Efficiency in operation and in management as well as in power plants and in machinery is now awakening interest and wide discussion. Electricity is the great modern means of securing efficiency in the applications and uses of power. The progressive men of manufacturing companies and of central stations are beginning to recognize this and through their efforts it is beginning to impress itself upon the public. The problem is a tremendous one, its solution means much for the public, for the central station, and for the manufacturer, and it merits united effort in its solution.

III.—Commercial.

In their commercial prosperity and success, as measured by the earning of dividends, the manufacturer and the central station have much in common. One supplies apparatus, the other operates it, and together they contribute to supply a growing need of the community. The central station is no longer a novelty supplying current within a radius of a mile or so to those who can afford the luxury of an incandescent lamp upon a combination fixture where the gas can be lighted when the current fails, for in recent years small companies are uniting into large systems. Hence, light is no longer a luxury, and the company is called a Public Service Corporation. It is recognized, both practically and legally, as an institution which supplies a fundamental need by rendering a public service to the community. Government commissions see that the public is provided with an adequate service at fair rates and also that the company is protected against unjust competition and that it secures rates which are fair and adequate.

Moral and legal obligation, as well as good business policy, dictate that the central station should supply the best possible service and should extend that service in the public interest as well as its own interest. This means that the central station must provide a reliable and continuous service ; that it must not merely be ready to supply current, but that it must also render a public service in showing how to use electricity and how and what direct and indirect gains follow from its use, and further, it must develop its equipment and its organization to meet the larger field of service which the universal use of central station power will make necessary.

Continuity of service has a new importance for not only lamps, but street cars, elevators, mills, factories, the conveniences and necessities of the store, the office and the home are dependent upon electric power. Fundamental to such service is good apparatus. Some of the ways in which the central station can co-operate with the manufacturer in designing and manufacturing such apparatus have already been considered. There is, however, another, the commercial standpoint.

Commercial Standpoint.

The central station in fairness to its patrons and for its own success requires the best possible apparatus. Differences in first cost are trivial. The loss of direct revenue from a short interruption to service (not considering loss of prestige and the cost of repairs) will much more than compensate for the difference between the cost of inferior apparatus and the cost of the best. Not only should the best apparatus be bought, but it should command a fair price. The manufacturer who makes the best should be supported and he should be encouraged to make his apparatus still better.

In the applications of power which have been considered under "Commercial Engineering," it is to the common interest of the user, the central station and the manufacturer that the results should be successful. This means that adequate apparatus must be properly applied. From the standpoint of the customer, reliability and continuity of service are of first consequence. These depend, first of all, upon the quality of the electrical apparatus which is used. As the first cost of this apparatus is insignificant compared with the cost of the power it uses and the value of the products which it aids to produce, quality and not price is of first importance in the installation of a motor. Whatever the central station can do to aid its customers in securing good motors, whatever it can do to support the manufacturer who makes good motors and to induce the making of still better motors, contributes to the best interests of all concerned. The central station and the manufacturer together, by educating the public to the use of electricity in the right way on a sound engineering basis with the best apparatus are laying the surest foundation for their commercial success.

Progress Outlook.

Looking to the future, there is a wonderful outlook for the central station if we may estimate the future by the past. Twenty years ago, arc lights, incandescent lamps and street railways were operated from three different types of generators, few of which exceeded a few hundred k.w. in capacity. Ten years ago the steam turbine was being talked about and power load from central stations was beginning to be seriously considered.

To-day, the polyphase alternating current generator supplies electric service of every kind and it is demonstrated that the large central station plant is the cheapest to install, the cheapest to operate and the most reliable in the service which it gives. The uses of power are extending, isolated plants are disappearing, the domestic uses of electricity for light and heat and power are increasing, innumerable appliances for using electricity are constantly appearing, the railway terminals of the great steam roads and the electrical operation of suburban and trunk line service are matters of the immediate future. The central station should be the source of power for all purposes.

Future Policy.

To insure that the electrical progress of the next decade will keep pace with that in the past, the central station must meet the new demands for reliability, and for a broad comprehensive expansion of its activity and its policy. Apparatus larger in output and better in quality will be demanded for generating, controlling and using electric power in all forms. The experimental investigation and the practical development of apparatus has been carried on in the past largely by the manufacturing companies. They have expended millions of

Bronze Casting, 5 ft. Diameter, 12 ft. Long.

dollars in developing new and better apparatus and the central station has reaped the direct benefit. Such work must go on; it must be aided both by engineering co-operation and by the commercial endorsement of the central station interests.

Modern civilization has been brought about by the steam engine, through its effect on transportation and manufacture. Electricity is bringing about a new power era, because it facilitates the generation, the transmission, the distribution and the universal application of power. The central station is the agency for supplying this power. Upon its progressive policy in acting with the manufacturer of apparatus on the one hand, and the public on the other, depends the commercial prosperity of manufacturer and of central station, and the general welfare of the community, whose industries and transportation and daily life are becoming more and more dependent upon electric power.

A LARGE BRONZE CASTING.

The illustration shows an interesting and an exceptionally large bronze drum casting. The drum is 12 feet long, 5 feet in diameter, and is used as the drying surface in a large vacuum rotary drum drier.

The drums for this purpose are generally made of dense air-furnace iron, but in this case it was necessary to use a high quality bronze drum, a circumstance due to the fact that the vegetable extract to be dried on the drum would become discolored if it came in contact with iron.

The mold for this casting was swept up in dry sand, the core being swept up in loam. When the casting was poured, the mold was in a vertical position, thus accounting for the very clean surface free from blow-holes.

It required 16,000 pounds of metal to pour the casting and on account of this large quantity it was necessary to melt the metal in a 48-inch cupola.

The practice of melting bronze in a cupola is unusual, but the Buffalo Foundry and Machine Co., Buffalo, N.Y., the company which made the casting in question, has been very successful in following this practice where large quantities of metal are required.—Castings.

THE HAMILTON GEAR & MACHINE COMPANY.

The Hamilton Gear & Machine Co. have recently opened up a new factory on the corner of Concord and Van Horne Avenues, Toronto. The building, of modern concrete construction, is arranged to give the maximum natural lighting effects, and measures 50 by 55 feet. Ground adjoining has been secured for extension. Accurate cutting of spur and bevel gears is the firm's specialty, the equipment for handling same consisting of Gleason gear shapers, whose feature is theoretical accuracy.

So far as we know this is the only firm in Canada thus specializing, and from reports received of the work already on hand and in prospect, there is every reason to believe that a much-felt want is being taken care of.

A good way to fasten a wood handle onto a tool is to fill the hole full of shellac; then heat the shank of the tool almost red and press it home.—American Machinist.

CANADIAN MACHINERY
AND MANUFACTURING NEWS

A monthly newspaper devoted to machinery and manufacturing interests mechanical and electrical trades, the foundry, technical progress, construction and improvement, and to all users of power developed from steam, gas, electricity, compressed air and water in Canada.

Vol. VII. July, 1911 No. 7

RELIABLE EQUIPMENT.

In another section of this issue will be found an article in which the writer makes a plea for "Co-operation between the central station and the manufacturer." It is not our intention to dwell on that particular topic, rather is to draw attention to certain definite suggestions made by Mr. Scott, and which are worthy the serious attention of manufacturers and all others who use electric power, electric light, or heat by electricity.

We are rather inclined to believe that the tendency to cheap equipment and saving of light is more predominant than otherwise, and the careful reading and study of what Mr. Scott makes so clear and convincing should tend to a more reasonable attitude being adopted on the part of all concerned. First cost, although needs be high, is not by any means the prime factor in the power and lighting instalation of any manufacturing concern, but rather is it, as aptly put in the paper, "a problem not to save power, but to use power effectively." We believe the advice and information given, to be appropriate and well timed, and look for highly beneficial results in the matter of their adoption and practice.

THE EFFICIENCY QUESTION.

In common with other technical and trade journals, we are giving our readers opportunity to become familiar with the ideas and publicly-expressed views of men who have devoted much time and study to this presently all-absorbing topic.

One feature prominent in the various phases of the subject is the easily appreciable grasp that men of moderate intelligence can take, digest and give reasonably correct and reliable opinions as to the worth or otherwise of any particular scheme.

Carefully-drawn observation is the basis from which individual ideas for betterment have originated, therefore, mathematical calculation and intricate formulae are for once, conspicuous by their absence, in spite of the word "scientific" bearing a qualifying relation. The various views expressed make interesting reading, are educative, yea helpful, because the reader feels that strings are being tuned with which his own are to a large extent in harmony.

The tendency of this efficiency movement is undoubtedly for all-round betterment, and while, like every other reform or revolution, for such it is, large progress may tarry, we may rest assured that it is gathering momentum all the while, and that out of the multiplicity of schemes and ideals propounded, new and improved conditions will arise.

A QUESTION OF FINANCE.

Much keen competition is apparent in every department of our business life to-day, and, digressing, we may say that it exists to an equal extent in social and church circles. Money, the purchaser of comfort, luxury, position and honor, is king, and rules with a hand of iron. This money determines the price to be paid for some cherished idol, from the hoard we possess, and when we have no hoard or are living from hand to mouth, the degree of misery we must endure.

It is our purpose to draw attention to this latter aspect, as it affects what we might term the small manufacturer, in his capacity as "feeder" to the large corporation.

This is a day of mergers and mammoth enterprises, having large administrative staffs; a day in which the "little fellow" is either swallowed up or forced to the wall. These two latter contingencies seem to us somewhat unfortunate, not only because it cuts the feet from personal effort, but because of the tendency towards complete extermination of a business necessity.

Big manufacturers don't realize sufficiently, nor appreciate as they should, the service these small concerns render them, especially during periods of great activity, when to avoid starting a number of extra men temporarily to cope with the rush, it is a convenience to send part of the work out, and have it executed by the "feeder." Just here is where the crowding-out takes effect, and the instrument used is delayed payment for work done. No thought is given to what is common knowledge, that these small business men have their cash almost wholly tied up in plant, that their employes' wages and trade accounts have to be met regularly (the latter more so perhaps than in the case of the big corporation) and that the banks are more chary, and look with a large measure of suspicion on overdraft requests; yes, in spite of the fact that hard work and honesty are distinctly visible.

We appreciate the labors of bookkeeping, and a like system of payment for all, if possible, nevertheless it is a hardship unspeakable for 95 per cent. of these "feeder" shops (patternmaking, molding, machine, etc.) to have to lay out of their payments, not only 90 days, as some require, but even 10 days. Give your "feeder" a chance, put betterment of this department of paying him one of your pressing propositions to be solved, and as a large corporation you will be helping to ensure a continuance of service you cannot well do without.

Boiler Design, Construction, Operation, Repairing and Inspection

By H. S. Jeffery

Repairing Boilers.

When applying a patch to a boiler the type of boiler has a marked bearing on the type of patch that should be applied; likewise how the patch should be applied. If the bottom of a tubular boiler

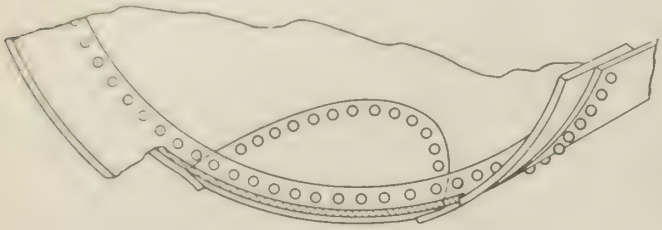

Fig. 27.

is defective and a small patch is to be applied adjoining the centre girth seam, a patch as shown in Fig. 27 should be applied. It is frequently called a horse-shoe patch. The illustration, Fig. 27, shows that having cut out the defective shell sheet, the girth seam rivets when replaced hold a portion of the patch in place. It is essential to scarf the plate at points A, Fig. 27, in order to cause no abrupt openings at the three thickness of plate.

If the shell plate is defective adjoining one of the flue heads and a patch, horse-

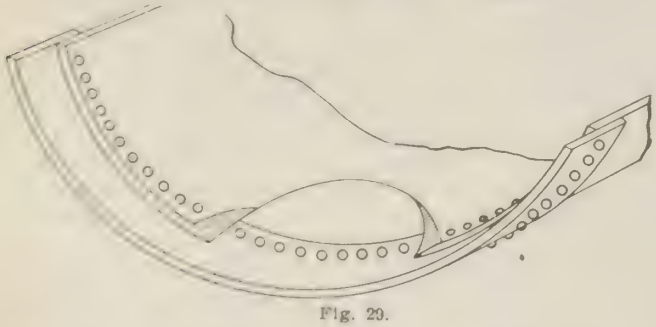

Fig. 29.

shoe style is applied, the corners A of the patch should be scarfed as described in the foregoing instance. This is illustrated in Fig. 28, this being the case whether the patch is applied to the large or the small course of the boiler.

The patch, Fig. 27, is an illustration of a patch applied to the large course of the tubular boiler. If the patch is to be applied to the small course of the boiler the method is similar, except the shell sheet is scarfed instead of the patch. This is illustrated in Fig. 29, the points A being scarfed. If the sheet is not scarfed as indicated in Fig. 29, then the patch when applied would have an offset as indicated in Fig. 30 at the points A.

The object of the horse-shoe type of patch is to prevent placing in the longitudinal plane a single riveted joint. Such a patch, and in fact every patch applied to the bottom of a tubular boiler should be riveted in place—never apply with patch bolts. The shell of a tubular boiler is a vessel, and, accordingly differs from the firebox of a locomotive boiler or the combustion chamber of a marine boiler, where a patch can be applied with patch bolts.

The shell of a tubular boiler when under steam pressure is under tension—that is, forces acting upon the shell tending to pull it apart. Now, with the furnace sheets of a locomotive type boiler, the chief consideration is to keep the plates from deformation, or bulging. For this reason staybolts are placed at given intervals, thus supporting the sheet to carry the load.

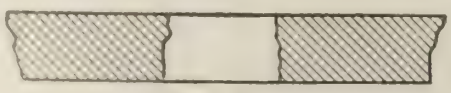

Fig. 31.

The firebox or the furnace sheets of locomotive, traction and other types of boilers, crack from staybolt hole to staybolt hole. The causes leading to the cracking are many. The punching of the staybolt holes frequently cracks or fractures the plate around the holes, this being especially true if the holes are punched with a dull punch and a large die.

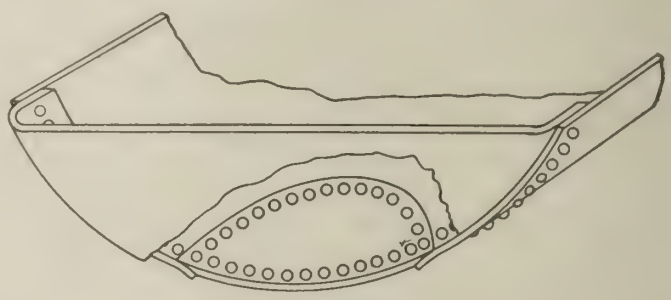

Fig. 28.

Punched holes make a rough and irregular hole in the plate as indicated in the illustration, Fig. 31. For this reason many authorities require that all rivet holes which are punched shall be punched one quarter inch or so smaller than the diameter of the rivet to be used and then reamed out.

While this practice is carried out by many in regard to rivet holes, it is not carried out extensively throughout the country in regard to staybolt holes. The common every day practice seems to be to punch the staybolt hole about one-eight inch less in diameter than the diameter of the staybolt—some punch the hole three-sixteenths less in diameter than the size of the staybolt.

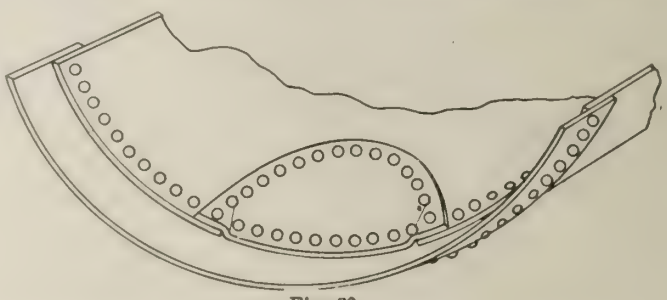

Fig. 30.

While the furnace sheets are usually light compared to other sheets of the boiler—and they are made thin to make easy transmission of the heat through the plate to the water within the boiler

the staybolt holes are nevertheless irregular if punched, though not so irregular as rivet holes in heavy plates.

The fracturing of the plate by punching permits a starting point from which the crack extends and many times extends from staybolt hole to staybolt hole. At the outset the crack may be repaired by placing in the sheet a small plug as indicated in Fig. 32. A small hole is drilled into the crack, after which the hole is tapped and a plug screwed in and then riveted and calked over. The number of plugs depends upon the length of the crack, and where more than one plug is required, it is the practice to install the plugs so that they overlap.

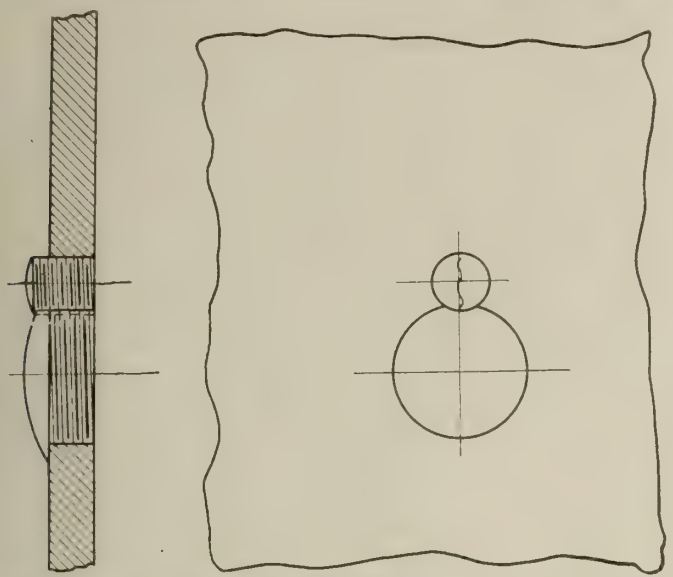

Fig. 32.

Thus if a crack one inch long is to be plugged, the first plug would be the plug A, Fig. 33, which would be placed at what was supposed to be the end of the crack, though this point is often hard to ascertain, for the crack may be of a character that it cannot be fully traced from the side or point from which the examination is made.

After plug A is installed, then plug B is installed, after which plug C is installed. It will be seen that plug C overlaps plugs A and B, and after all the plugs are installed they are riveted and calked over to form a ridge, the whole process being known as SEWING UP A CRACK. The plugs are usually about three-eighths inch in diameter and threaded twelve threads per inch.

POWER EQUIPMENT & APPLICATION

Expert Descriptive Articles Dealing with Selection and Purchase of Most Suitable Power Equipment for All Purposes, its Proper Application, Installation, Operation and Treatment.

SPUR GEARS.

By G. D. Mills, Montreal.

IN introducing this article on Spur Gears, the writer has aimed to provide a reliable guide for the designer or manufacturer, together with a collection of reference tables and formulae, which can be followed with confidence.

Classification of Spur Gears.

Spur gears may be classified as Gears connecting parallel shafts by teeth which mesh as they roll on their axis. The proper arrangement of the teeth is accomplished by means of tangent circles, known as the pitch circles of the respective wheels. On these lines the teeth are wove, so that they mesh correctly, and have sufficient space at the tooth bottom to clear each other. The pitch circles, although merely constructional, are nevertheless the most important lines in the design of spur gears, and always define the centre of the working depth of teeth.

The addendum or upper half of the working depth of tooth therefore projects from each pitch circle, and meshes with the addenda of the mating wheel, which is equal to it in length. The working depth of tooth is addendum x 2, and by adding clearance, we get the total depth of tooth.

Tooth Parts and Wheel Dimensions.

In the diagram Fig. 1, will be found two tangent pitch circles, as in all spur gears. Fig. 1 is an explanatory diagram, describing the tooth parts and dimensions of wheels. The radial lines denote the tooth centres; the circular pitch being the circular distance from the centre of one tooth to the centre of the tooth adjoining, measured on the pitch circle. The width of tooth is one-half the circular pitch in cut gears, and the table of tooth formulae is arranged so that any part may be readily determined in a variety of ways, thus giving wide scope to ready calculation; a convenience appreciated by those who have practical designing to do.

The diametral pitch is the standard which governs all tooth dimensions, and represents the number of teeth to each inch of pitch diameter. It is the pitch number of the wheels. With any one diametral pitch, we are obliged to have the same circular pitch, addendum, clearance, full depth, and width of tooth, irrespective of what the pitch diameter or number of teeth may be. From this it will be seen that we have three quantities to consider in designing spur gears; the number of teeth, pitch diameter and diametral pitch, which is essentially the size of tooth. The pitch diameter and number of teeth bear equal proportions, and the diametral pitch is the ratio of the pitch diameter and number of teeth. Its reciprocal is the addendum, or one-half the working depth of tooth. The relations which the pitch diameter, number of teeth, and diametral pitch bear to one another are expressed in the formulae

$$P=\frac{N}{D} \quad D=\frac{N}{P} \quad \text{and} \quad N=D.P.$$

The relation which the addendum bears to the circular pitch is, as the diameter of a circle

to its circumference, or the addendum multiplied by 3.1416, equals the circular pitch. The tooth formulae represents the best modern practice in gear design, and should be followed carefully.

Basis of Calculation.

In Spur Gears we have a variety of conditions and our calculations are based mainly on the speed ratio required for the gear and pinion. We may have the pitch diameters to determine from the distance between centres and speed ratio, or the distance between centres can be calculated from the number of teeth in the wheels and the diametral pitch. It may also be necessary to calculate the strength of the teeth in the wheels. Accompanying is a table of tooth parts arranged from 1 to 10 diametral pitch, and from this table any size tooth may at once be selected, and its diametral pitch

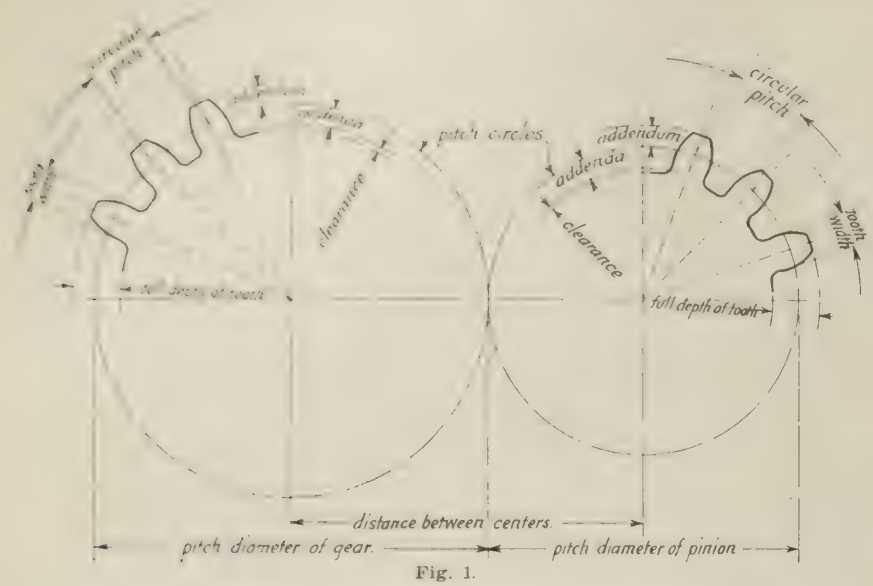

Fig. 1.

ascertained. If the desired diametral pitch is not in the table, its parts can be found by dividing the parts of 1 diametral pitch, by the desired diametral pitch, and while gear cutters are usually arranged in even diametral pitches, there are some cases in which an even diametral pitch will not answer. Should the conditions call for a pitch diameter and speed ratio that will not permit of an even diametral pitch, it will be necessary to have a special cutter or two made to cut the wheels.

The face length of teeth is said to be in good proportion, when it is 2½ times the circular pitch. This, however, is variable, as it may be desirable in the case of light loads to reduce the length in order to effect a saving in material and space, or to increase it, to carry heavy loads. The face length of teeth is part of the formulae for ascertaining the strength of gear teeth, and is treated later on. The formulae for determining the pitch diameters from the distance between centres and speed ratio is as follows:

$$\text{Pitch diameter of gear} = \frac{C}{R+r} \times r \times 2$$

$$\text{“ “ “ Pin.} = \frac{C}{R+r} \times R \times 2$$

In which C=distance between centres.
R=ratio term of gear.
r= “ “ “ pinion.

If the speed ratio was 5 to 1, the ratio term of the pinion would be 5, and that of the gear 1. The distance between centres may also be determined by the formulae.

Tooth Parts.

Diametral Pitch	Circular Pitch	Thickness of Tooth	Addendum	Depth of Tooth	Working Depth	Face of Tooth

Gossip of the Trade

The Canada Metal Co. have moved into new and spacious premises on Fraser Avenue, Toronto, from whence they will continue to send out their numerous well-known brands of babbitt metal, phosphor bronze, copper ingots, etc. The business was started 30 years ago on William Street, Toronto, by W. G. Harris, president of the company, and has gone steadily ahead since, until it is now favorably known from coast to coast. The Canada Metal Co. makes a number of brands of babbitt, one of the best known being the Harris Heavy Pressure brand, designed especially to overcome the troubles of soft bearings that squeeze out, and of hard bearings that crack in the box or cut the shaft.

The Smart-Turner Machine Co., Hamilton, report the following orders recently received: H. J. Hogan, Port Colborne, Duplex pump; Samuel McMahon, Revelstoke, B.C., single-acting vertical power pump; the Alabastine Co., Caledonia, rotary pump; the St. George Condensary Co., St. George, steam pump; the Sincennes-McNaughton Line, Montreal, Que., side suction centrifugal pumps; the Corporation of Grimsby, centrifugal pump; the Hamilton Oak Tanning Co., Woodstock, Ont., horizontal duplex power pump; Gunns, Ltd., West Toronto, side suction centrifugal pump, direct connected to motor; the Page-Hersey Iron Tube & Lead Co., Guelph, single-acting triplex power pump; Wm. Clark, Montreal, side-suction centrifugal pump; the Trenton Canning Co., Trenton, Ont., duplex pot valve pump; Thos. Ivey & Sons, Port Dover, duplex double-acting power pump.

The Canada Steam Pump & Machine Co., 97 Richmond St. E., Toronto, recently completely overhauled the turbines and auxiliary machinery of the S.S. Turbinia, which plys between Toronto and Hamilton. After running for seven or eight years some parts of the machinery had got into poor shape, one of the centrifugal circulating pumps being considerably out of balance, necessitating a new shaft. The original shaft had worn one inch below size. The pistons of the high-speed engine driving the centrifugal pumps were worn 3-16-inch, and owing to the shortness of the connecting rods, together with the slackness of the cross-heads and gudgeon pins, the cylinders themselves were badly scored, and had to be re-bored. A new feed water heater was also installed and the whole equipment put in first-class shape.

SYSTEMATIC BUSINESS MANAGEMENT

Practical Articles for Managers, Superintendents, and Foremen, to Assist in Carrying on the Business Economically and Efficiently.

LIMITATIONS ON SCIENTIFIC EFFICIENCY.*

By Henry G. Bradlee.**

IT would, no doubt, be presumptuous at this time, said Mr. Bradlee, to place a limit on what may be accomplished in the future through efficiency methods, and certainly no one would wish to criticise or suggest weak points in these methods, were it not for the fact that the public may be misled by exaggerated statements and may unreasonably condemn those who are doing most to develop and direct our industries. In view of the statements which have been made, it certainly seems reasonable and proper for us to consider whether there are not some practical limitations which have prevented a general adoption of these methods in the past, and which may prevent the wholesale overturning of our present industrial system prophecied by certain efficiency engineers.

Efficiency Engineering Methods.

Stripped of technicalities, the method of the modern efficiency engineer is simply this: First, to analyse and study each piece of work before it is performed; Second, to decide how it can be done with a minimum of wasted motion and energy; Third, to instruct the workman so that he may do the work in the manner selected as most efficient. There is nothing fundamentally new in all this. The underlying principle is being used to-day to a greater or less extent in all industries, and has, no doubt, been used at all times in the past. Let us keep this fact just as clear in our minds as possible.

The method employed by the modern efficiency engineer is distinctive, not because it is new, but because it embraces much greater detail. As I have already indicated, we are all familiar with the general principles underlying the modern methods; and many of us make frequent use of these principles in the conduct of our business. I think I am correct in saying that in the business with which I am connected, every general principle and every detail method which has been suggested by the efficiency engineer has been used at one time or another, and many are in use to-day. The subject is then a familiar one to all of us; the problem presented is not the adoption of something entirely new, but rather the extension to every detail of our work of something which we have already tried.

When we look at the matter in this light, we naturally ask ourselves, is it in all cases practical and desirable to extend these methods to all parts of our work, and if not, under what circumstances may it be done to best advantage? It would be impractical to fully answer these questions within the limits of a short paper, but we may suggest very briefly a few factors which seem likely to limit the practical working field of the efficiency engineer.

Examples of Highest Efficiency.

Scientific management will clearly yield its best results when the labor performed consists of a continuous repetition of some definite set or series of sets, and when the work is carried on under conditions which remain practically uniform. The second important factor is that the work of the different employes shall be reasonably uniform in character and not extremely diversified. Further, the extent of territory which a business covers may make it difficult, or entirely impracticable, to use the methods which give greatest success when applied to a group of men working in a single building.

Where, then, shall we look for work to which efficiency methods may be successfully applied? Where can we find a considerable number of men, located near together, preferable in a single building, all doing the same kind of work under conditions which remain practically uniform, and the work itself consisting of a continued repetition of some definite act or series of acts? Work of this character will presumably be found in certain mills, factories and shops, and in some special departments of other industries. These are the places, then, where we may expect the efficiency engineer to meet with the greatest success, and if we may judge from the examples quoted, it is in just such places and under such conditions, that the best results have so far been secured. When we have given the limitations the consideration they deserve, I think we will reasonably conclude that we are not likely to see any sudden and remarkable increase in industrial efficiency.

The efficiency engineer may easily prejudice his own cause by making exaggerated claims and statements of what he can accomplish. He may discredit his own profession by criticizing too freely the work and methods of others or by rashly condemning the efficiency of our present industrial organization.

*Abstract of paper presented before the Congress of Technology at the Fiftieth Anniversary of the Granting of the Charter of the Massachusetts Institute of Technology.

SCIENTIFIC INDUSTRIAL OPERATION.*

By Tracy Lyon.**

IT is natural to assume, said Mr. Lyon, that when a man has worked at one task for years, whether on a machine tool or at manual labor under ordinary competent supervision, and with the advantage of his own experience and trade traditions, he has reached a degree of skill and speed which could be increased by expert instruction to only a small degree. But this is not so and therein lies the keynote of scientific management. It has been demonstrated that a man can be taught to double or even quadruple his output, with no greater, and with even less physical exertion, by means of a use of tools and a distribution of effort, which unaided he would be incapable of evolving.

Conditions Necessary to Efficiency.

In order to bring out the best and most intelligent effort on the part of most men, it is necessary to establish and recognize a reasonable measure of their efficiency, and to develop same to its highest degree. Further, there must exist methods of compensation which will offer comparatively large returns for increased individual effort and an organization which will effectively plan in advance, to bring together at the right time all information, tools and material required,, and in addition, furnish adequate instruction and supervision with carefully considered arrangement of appliances and machinery to bring about the economical movement of work. A very essential function of such an organization is to create a feeling of co-partnership between employer and workman, and an understanding that the employer is not trying to get the most work for the least wage, but is willing to pay liberally for increased output and efficiency.

Many manufacturers do not know what the real and actual cost of their product is, particularly if it is diversi-

*Abstract of paper presented before the Congress of Technology at the Fiftieth Anniversary of the Granting of the Charter of the Massachusetts Institute of Technology.

**The Westinghouse Electric Co., Pittsburg, Pa.

fied, because of a lack of adequate cost accounting and because the overhead or general charges are not properly distributed. This is to their own detriment as well as to that of the public, and while not an easy question to solve, there are, nevertheless, scientific methods of accomplishing it. I believe that railroads, for instance, would purchase many articles they now manufacture if they had a truer knowledge of their shop costs. Railroad shops have no balance sheets to face, and do not necessarily go out of business if they are not making money.

NEW STEEL PLANT IN OPERATION

The National Bridge Co. of Canada, which was organized in December last, and work first started on its new buildings near Dominion Park, Longue Pointe, Montreal, has made its first shipment of finished steel. Power was turned on a few days ago, and the shop machines put in operation, resulting in the first shipment for customers' contracts, within about 48 hours from the start.

This is a new record in rapid construction, for a large industrial plant in the Dominion.

AN INTERESTING REPORT ON CANADIAN TRADE.

His Majesty's Trade Commissioner for the Dominion of Canada, Richard Grigg, has just made a report to the Board of Trade, at London, England, on the trade of the Dominion of Canada for the period from July 1, 1906 to March 31, 1910. The report covers nearly every phase of Canadian operations and is divided roughly into three parts:

(1) A general survey of the economic conditions of the Canadian market.

(2) The import trade of Canada.

(3) A survey of particular branches of trade.

Trade conditions for the period named are analyzed very carefully and the figures relating to labor and to some of the principal commodities used by engineers and contractors are of practical interest.

LARGE FAN.

One of the largest fans yet made is illustrated herewith. It is over 32 feet high, and was made by the Buffalo Forge Company. It is used in connection with a heating, ventilating and air conditioning system, supplying 25,000 cu. ft. of air per hour to every employe in the new mill of the Sharpe Mfg. Co., New Bedford, Mass., the largest individual yarn mill in that city.

In this mill particular consideration has been given to the hygienic conditions of operation. The air is washed before entering the mill, all dust, dirt and foreign matter being removed; leaving the air absolutely clean. In winter the air is heated to any desired temperature, a feature being independent regulation on each floor. Provision is also made for cooling the air, so that in the hottest days of summer the temperature throughout the mill, even in the spinning room where the machinery generates an immense amount of heat, will be from 15 deg. to 20 deg. cooler than is possible by ordinary window ventilation.

The volume of air that the fan handles to achieve these results reaches the astonishing total of 20,000,000 cu. ft. per hour. The conditions thus obtained are as near ideal for this kind of work as it is possible to make them.

Buffalo Forge Co. Fan.

Catalogues

We have received from H. W. Petrie, Ltd., Toronto and Vancouver, a copy of the 1911 edition of their machinery catalogue. The contents run to 156 pages, and set forth by text and illustration the varied and wide scope of the lines carried and the business handled. Careful perusal by those having to purchase equipment for large or small factories will be amply repaid by the mine of information it unfolds, and will instill confident assurance that even the most urgent requirements can be promptly met by Petrie, Ltd.

There is practically no line omitted from the list carried, which manufacturers daily require, and a copy of the catalogue on the purchasing agents' and superintendents' files will be a ready and reliable reference, carefully indexed. The firm, established away back in 1871, are keeping pace with and anticipating Canada's growth, and much credit is due to Mr. H. W. Petrie, whose photo appears as frontispiece, for the development of a business which has become a household word in the mechanical and agricultural fields from coast to coast. Copies of the catalogue may be had on application.

The Chain Belt Co., Milwaukee, Wis., have issued a new edition of their general catalogue No. 40, descriptive of elevating, conveying and concrete machinery. It is handsomely bound in book form, and contains 278 pages of text and illustration, referring to the many adaptations of the firm's manufacture in the fields indicated. In addition to equipment details, cuts are shown of installations of various types and for various purposes, enabling those in the market to form a good idea of what their requirement should consist and where to get it. Copies of the catalogue will be mailed on request, to responsible firms or their representatives.

John Millen, Sons & Co., Ltd., Montreal, Toronto, Winnipeg and Vancouver, have forwarded us their 1911 automobile and motor boat supply catalogue. It is, as usual, a most creditable production in the matter of text, illustration and artistic treatment generally. Increased business and prospects in the above direction have warranted the firm in increasing the size, and thereby the scope of the catalogue. Such a step means, of course, increased stock carried, and the desire to meet every requirement.

Automobiles and motor boats have come to form a large part of our very existence to-day, and have a tendency to become less of a luxury than a few years ago. This being so, the myriad details applicable and necessary for these machines has an interest for an increasing purchasing field, and to have the opportunity always at hand and be assured of satisfaction, this catalogue should be secured and its contents carefully noted. Sectional divisions, A for automobile supplies, and B for those of motor boats, make, together with the complete index, ready reference always available.

The Consumers Gas Co., Toronto, is at present engaged in erecting the largest gas holder in Canada. The capacity is five million cubic feet, and the construction work was carried out by C. & A. Walker, Donnington, Shropshire, England.

INDUSTRIAL AND CONSTRUCTION NEWS

Establishment or Enlargement of Factories, Mills, Power Plants, Etc.; Construction of Railways, Bridges, Etc.; Municipal Undertakings; Mining News.

FOUNDRY AND MACHINE SHOP.

SACKVILLE, N.B.—Additional railway facilities have enabled the Fawcett Manufacturing Co. to discard the horses and carts which have been conveying their exports and imports over the mile of road between the Foundry and the I.C.R. Station, and they are now in direct railway communication with the Pacific Ocean.

KINGSTON, ONT.—The Canadian Locomotive Co. find their present plant entirely inadequate to handle present orders and are preparing to double its capacity.

OTTAWA, ONT.—The Department of Public Works has issued a call for tenders for work in the harbor of St. John, N.B., which will probably bulk up to $8,000,000 or $10,000,000.

Contractors are asked to put in bids for a drydock and ship-repairing plant of the first class, for dredging Courtenay Bay, for the construction of three steamship berths, and a breakwater. All are to be bid for in the lump.

REGINA, SASK.—The Farmers' Steel and Wire Co. have plans for a six-storey warehouse and plant for the manufacture of wire and steel work. Only two storeys and basement will be built this year.

CALGARY, ALTA.—The Gordon Nail Works of St. John, N.B., have definitely decided to locate here, not at Medicine Hat as reported.

HAMILTON, ONT.—Three important new concerns are locating here, namely the Taylor Manufacturing Co., of Princeton, Ind., makers of steel bar clothing racks, etc.; the Boston Insulated Wire and Cable Co.; and the Mayo, Brown Co., a local concern which will manufacture steel stamps, dies, stencils and kindred articles.

NEW GLASGOW, N.S.—W. P. McNeil & Co. are said to have work under contract aggregating over $400,000. The big contracts include a machine shop and forge building for the N.S. Steel and Coal Co., at Trenton, a new shipping pier for the same company at Wabana, a rail fishing building for the Dominion Steel Co., at Sydney, a machine shop and forge for the Canada Car Co., at Amherst, a highway bridge across Wallace harbor and several other bridges.

ORILLIA, ONT.—The Canada Refining and Smelting Co. are extending their plant and will add four brick, one concrete, and two wooden buildings.

WELLAND, ONT.—Experiments were conducted here recently in the smelting of pig iron by electricity.

MONTREAL.—Thomas O. Sinclair, engineer and coppersmith, has assigned for the benefit of his creditors. His liabilities are $4,991 and assets $3,384.

TORONTO.—The new dock of the National Iron Works was opened recently. The company are installing a crane and magnet for lifting iron and steel, 10 tons to every load.

COBOURG, ONT.—The Crossen Car Works are preparing to erect new shops here.

CHATHAM, ONT.—Several local capitalists have decided to form a company with $20,000 stock to manufacture motor trucks. The plant will be quite extensive.

CHILLIWACK, B.C.—The B.C. Electric Railway are preparing plans for the construction of car barns and machine shops.

FORT WILLIAM, ONT.—The Lumby-Stenhouse foundry on South Syndicate Ave., was burned with a loss estimated to be in the neighborhood of $2,500.

LUNENBURG, N.S.—The Lunenburg Foundry Co. have installed a new lathe built by R. MacDougall & Co., Galt, Ont.

NORTH BAY, ONT.—The C. P. R. will erect new shops at North Bay to cost approximately $500,000.

BRANTFORD, ONT.—The Cumback Motor Co. are assembling machinery for the turning out of 50 motor trucks and if these prove successful a factory will probably be erected.

WESTPORT, ONT.—The ratepayers have voted a loan of $10,000 to the Westport Foundry Co. and a bonus of $2,000. The foundry was recently destroyed by fire.

FREDERICTON, N.B.—The N. B. Foundry has resumed operations and is being operated by electricity.

SYDNEY, C. B.—Rhodes, Curry, Ltd. have the contract to erect the new $98,000 general office building for the Dominion Steel Co.

GALT, ONT.—The Galt Machine Screw Co., a new concern, have secured premises and will manufacture machine screws, cap screws, set screws, special screws and parts of bicycles, autos and electric appliances.

MONTREAL.—The plant of the newest of the large steel companies in Canada, the National Works at Longue Pointe, is completed. The machinery has been installed, and the electric power used exclusively in the operation of the plant is being supplied by the Shawinigan Falls lines of the L.H. & P. Co. No steam is used except for heating purposes.

The capacity of the plant is 20,000 tons per year, which will be increased to 40,000 by the addition of a new shop building next year.

PRESTON, ONT.—The new 150 h.p. generator recently installed at Clare's stove foundry has been successfully tested and put in operation.

HERBERT, SASK.—Messrs. H. Sharman and L. C. Barry, mechanical engineers, are opening up a machine shop here.

REGINA, SASK.—The C.N.R. are calling tenders for a 10-stall roundhouse, engine room, machine shop and turntable for this city. The machine shop will be of an approved type, 86 ft. by 38 ft., and of substantial construction. The corner of the shop will adjoin the roundhouse.

MILTON, ONT.—The Imperial Foundry Co. have been in operation over one month. They manufacture hot water and steam boilers for heating purposes.

WELLAND, ONT.—The Welland Machine & Foundries are now manufacturing gasoline

MALLEABLE IRON CASTINGS

PRATT & LETCHWORTH CO.
BRANTFORD ONTARIO

From 1 8 to 3 4 of a pound of
ALUMINIUM GRANULES
to the ton of steel will increase the tensile strength of your castings without decreasing the ductility—it will produce smooth faced castings and avoid blow holes—therefore will reduce your loss in castings to a minimum.
WHY NOT ASK FOR SAMPLES TO-DAY?
The British Aluminium Co., Limited
LONDON, - ENGLAND
General Agents: PARKE & LEITH, 60 W. Front St., TORONTO.

Jessop's Best Tool Steel
is yet unexcelled for cutting tools of all kinds, and for general machine-shop use.

Jessop's "Ark" High-speed Steel
gives marvellous results—heavy cuts -- at rapid speed; cannot be burned.

The favorite brands with users of good steel.
A large assortment of sizes in stock.
Jessop's high-grade files and rasps.

Manufactured by WM. JESSOP & SONS, Ltd. Sheffield, Eng.
Reid Newfoundland Co. St. John's, Newfoundland
Alex. Woods 138 Murray Street Montreal, Que.
Chas. L. Bailey 80 Bay St. Toronto, Ont.

Better Lubrication
means greater efficiency, less wear on engines and machines, reduced cost for operation and maintenance.
Dixon's Flake Graphite
produces all these results. It is the one lubricant that attacks friction at its source—microscopic roughness in the metal surfaces.
Our free booklet 223C tells you all about it,
JOSEPH DIXON CRUCIBLE CO. - JERSEY CITY, N.J.

engines, in addition to their regular line of contractors' machinery.

GALT, ONT.—E. Roelofson, formerly of the Parkin Elevator Co., of Hespeler is at the head of a new firm that will manufacture passenger and freight elevators.

HULL, QUE.—A company with a capital of $500,000 has been formed to locate a $100,000 plant here for the manufacture of a new drill or mine tester recently patented by C. Demerais, of this place. They will also build a plant in the States to cost $250,000. Associated with the patentee is H. W. Bagnall, of Ottawa.

WEYBURN, SASK.—C. J. Acton and W. B. Montgomery, of Carleton Place, Ont., are opening up an automobile garage and repair shop here.

SMITHS FALLS, ONT.—Rumor connects the Perrin Plow and Stove Co., with a contemplated merger, to be composed of a big wagon concern, a western steel truck industry and a large jobbing firm.

SYDNEY, C.B.—The Dominion Steel Corporation have placed the contract for a large nail mill to take the place of steel rod manufacture on which the bounty has been taken off.

FORT WILLIAM, ONT.—The Canadian Iron Corporation are preparing to extend their plant.

MONTREAL, QUE.—The Canadian Car and Foundry Co. will spend $200,000 extending their plant at Turcot and Dominion.

FORT WILLIAM, ONT.—$15,000 is being spent on a three-storey annex to the warehouse and machine shop of the Northern Engineering and Supply Co.

R. McDougall Co., Galt, Again Enlarge.

The R. McDougall Co., Galt, have let the contract for a new molding shop to Wm. Edmonds. The shop will be of brick and steel construction on a concrete foundation. This will double the capacity of the foundry.

MUNICIPAL.

DRESDEN, ONT.—The by-law to raise $16,000 for a waterworks system here was carried.

WELLAND, ONT.—W. H. Weller, of St. Catharines, has secured the contract for a portion of the increased waterworks power, the contract price being about forty thousand dollars. Contracts will be let later for pumphouses and other parts, the total expenditure being about seventy thousand dollars. This will give Welland town an entirely new supply of water and machinery for pumping. The old pumps and buildings will be kept as auxiliaries.

EDMONTON, ALTA.—That the city can erect and place in operation an artificial gas plant, equipped with the most modern machinery manufactured, at a cost not exceeding $230,000, is the substance of the report recently submitted to the city council.

QUEBEC, QUE.—The sum of $65,000 which was asked by the Waterworks Committee for improvements in Limoilon and in St. Sauveur was approved by the finance committee and recommended to the city council.

VANCOUVER, B.C.—R. S. Lea, of Montreal, has been appointed consulting expert engineer in connection with a comprehensive main drainage scheme for greater Vancouver, including the adjacent municipalities of Point Grey, South Vancouver, Burnaby and all the district between Burrard Inlet and the north arm of the Fraser River.

PORT ARTHUR, ONT.—The following by-laws, aggregating $163,755, will be submitted to the judgment of the burgesses: $6,000, improvements to municipal buildings; $10,000 towards construction of bridge over Current river; $9,000, extensions of telephone system; $17,250, extensions of street railway system; $16,505, sidewalks and streets; $75,000, extension of waterworks; $30,000, completion of storage dam at Current river. There will also be submitted a by-law to guarantee the bond issue of a company to be incorporated by J. L. McRae, to the amount of $30,000, and a by-law to provide that the city shall assume the sum of $149.70 annually for 18 years, local improvement charges for the widening of Banning Street; also a by-law to authorize an agreement between the city and R. B. McArthur, and to guarantee bonds to the amount of $35,000. Voting takes place on July 6.

SUSSEX, N.B.—A by-law to raise $15,000 for improvements and extensions to waterworks and sewerage systems has been approved by the ratepayers.

BRANDON, MAN.—The ratepayers have approved the by-law extending the franchise of the Brandon Gas Co. from 20 to 30 years, and the by-law to raise $25,000 by way of debentures for the purchase of rails for street railway.

BRIDGEBURG, ONT.—A by-law will be submitted to the ratepayers for approval, providing for sewer extensions, $8,000.

CALGARY, ALTA.—Negotiations are under way by which the Calgary Gas Co. will amalgamate with the Prairie Fuel Gas Co., and thus, if the amalgamation goes through, all the gas companies in Calgary will be under one head.

CAMROSE, ALTA.—The ratepayers carried the waterworks by-law here recently and it is hoped to have the system completed by next fall.

KAMLOOPS, B.C.—The following bylaws were carried by large majorities; $30,000 for extension of waterworks; $10,000 for extension of sewerage systems; $20,000 for automobile fire apparatus and an appropriation to buy a second lot for a large addition to the drill hall.

ST. MARY'S, ONT.—W. S. Brook, C.E., of Toronto, has prepared plans for a new sewerage system for this town.

NIAGARA-ON-THE-LAKE, ONT. — The Village of Niagara-on-the-Lake intends to have a waterworks by-law and, if possible, it is going to get the Government to pay part of the expense of the work, which is estimated at $21,500. The council has proposed to the Government that it should pay $1,000 as an annual rental for the supply of water at the military camp grounds.

WELLAND, ONT.—The citizens have carried a by-law to spend $75,000 on additions and extensions to the waterworks plant.

RIDGETOWN, ONT.—The waterworks by-law calling for a $35,000 system was carried here recently.

MONTREAL, QUE.—City Engineer Janin asks $4,000,000 for permanent works, including many miles of sewers for the new wards.

ELECTRICAL.

EDMONTON, ALTA.—The city has given the Allis-Chalmers Co. an order for machinery to cost $42,000. They will install a new 2,000 K.W. unit.

NIAGARA-ON-THE-LAKE, ONT .—The by-law submitted to the ratepayers to grant a franchise to the Frontier Electric Railway, was carried.

VICTORIA, B.C.—The municipality will spend $50,000 to extend and complete the lighting system.

BLYTH, ONT.—$5,000 will be spent for a steam pump and electric light purposes.

HAMILTON, ONT.—A by-law based upon the report of E. J. Sifton, the electrical expert engaged to estimate on the cost of a civic lighting and power distributing system, will be submitted to the ratepayers July 25th. It calls for an expenditure of $505,160.

MONTREAL, QUE.—Arrangements concluded here, resulted in a group of prominent Montrealers securing control of the largest water powers in the vicinity of Prince Rupert, the Pacific terminus of the G.T.P. railway. The local interests are headed by C. H. Cahan, K.C., president of the Western Canada Power Co. and H. A. Lovett, K.C. They will form the Prince Rupert Hydro-Electric Co., capitalized at $5,000,000, of which $3,000,000 has been issued. It is the intention of the company to develop about 1,500 h.p. by means of a provisional power plant to supply the immediate demands of the city of Prince Rupert, and to proceed to the construction of a permanent installation, capable of supplying 15,000 h.p. so soon as the G.T.P. railway is running into its Pacific terminus. The company will also control gas works in the city of Prince Rupert and will install a gas-producing plant capable of supplying 75,000,000 cubic feet of gas per annum for light and heating purposes.

VANCOUVER, B.C.—Tests are to be made on the new incinerator, now on a series of trials for general garbage destruction, with a view to ascertaining the possibilities of the machine for developing power for heating and lighting purposes.

PETERBOROUGH, ONT.—The Otonabee Power Co. are spending $200,000 to increase its equipment. A new plant with an estimated output of 4,000 h.p. will be installed.

SARNIA, ONT.—The ratepayers will be asked to vote in favor of a municipally-owned electric light plant.

EDMONTON, ALTA.—A by-law to provide $100,000, the expenditure for the initial work on the municipal power plant at Grand Rapids on the Athabaskan River, about 200 miles north of Edmonton, was defeated by an overwhelming majority. Citizens believed the scheme, which will cost between $3,000,000 and $4,000,000, too big a one for the city at the present time.

WEYBURN, SASK.—The town council have had under consideration the advisability of supplying a day current of electricity to those desiring to avail themselves of same and at the regular meeting held recently it was decided to put the plan in operation as soon as possible.

MILLTOWN, N.B.—A Toronto concern is anxious to establish an electric power and heating plant in Milltown, and has asked the town council for the privilege of installing and operating such a plant.

GENERAL MANUFACTURING.

CHATHAM, ONT.—A sugar factory with a daily capacity of one thousand tons will be built here. D. A. Gordon, M.P., of the Wallaceburg and Berlin factories, is interested.

ST. MARY'S, ONT.—The Hunt Engineering Co., of Iola, Kansas, have been engaged by the St. Mary's Portland Cement Co., composed largely of Toronto capitalists, for the construction of a building and plant with a daily capacity of 1,200 barrels.

WINNIPEG, MAN.—The Gilmour Soap Co., of Montreal, contemplate establishing a branch here.

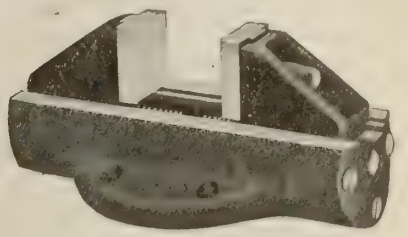
TORONTO, ONT.—The E. W. Gillett Co. will build a new plant at a cost of $250,000.

WELLAND, ONT.—Frederic B. Stevens, Toronto and Detroit, recently supplied to the Quality Bed, Ltd., Welland, Ont., one No. 28 Collian cupola; to the Jones Machine Co., Chattanooga, Tenn., one No. 28 Collian cupola, and to the Sherwood Brass Works, Detroit; the Universal Motor Truck Co., Detroit; the Buting Brass & Bronze Co., Toledo, installations of the injector sand blast systems.

The Montreal branch of the H. W. Johnsmanville Co. moved from their offices in the Eastern Townships Bank building, Montreal, on May 1st, to a new location, No. 450-452 St. James Street. The building has five floors, and a full stock of their entire line will be carried.

John Sabin, formerly manager of the Bundy trap department of the American Radiator Co., Boston, has resigned to become general sales manager of the Nashua Machine Co., of Nashua, N.H., who have taken over the sales agency of the Bundy trap.

BUILDING NOTES.



VANCOUVER, B.C.—C. F. Perry has plans for a seven-storey brick block 50x120 feet with stores on the ground and apartments upstairs.

TORONTO, ONT.—A handsome modern office building will be erected at 48 Adelaide Street East, on property recently acquired by Hon. J. H. Phippen, K.C.

VANCOUVER, B.C.—Albert Des Brisay will erect a six-storey brick building at a cost of $75,000. The first two floors will be utilized

VANCOUVER, B.C.—Grant and Manderson have prepared plans for a five-storey block for A. Williams.

FORT WILLIAM, ONT.—The Oddfellows propose erecting a fine new building here. It will be equipped with the latest sanitary fixtures. Steam heat will be used throughout and an elaborate ventilating plant installed. Architects Hood & Scott, of this city, are in charge.

VICTORIA, B.C.—The Hudson's Bay Co. have purchased a site here and will erect a thoroughly up-to-date departmental store, the largest west of Winnipeg.

VICTORIA, B.C.—H. S. Griffiths has prepared plans for a six-storey block here to cost $80,000.

FORT WILLIAM, ONT.—The C.P.R. will spend $3,000,000 on improvements here, including a coal dock, wharf and plant capable of storing 1,000,000 tons of coal.

TORONTO, ONT.—A Montreal syndicate will spend $180,000 on an artificial ice rink here, on the present site of the Mutual street rink, which they bought for $120,000. The syndicate is composed of W. Wylie, R. Bedford, A. C. B. Claxton, Mr. Boswell and a number of others prominent in Montreal financial circles.

TORONTO, ONT.—Frank Wilson has secured a permit for a 9-storey office building to cost $125,000 at 77 Adelaide street west.

TORONTO, ONT.—The Toronto Furniture Co. have taken out a permit to build a $70,000 factory here.

PLANING MILLS.

DEER PARK, B.C.—Mr. Kenna, of Everett, Wash., representing a number of saw mill men, was here recently with a view to establishing a saw mill.

REVELSTOKE, B.C.—The Bowman Lumber Co.'s mill and plant, valued at $50,000, together with about five or six hundred thousand feet of storage logs, were destroyed by fire.

CRANBROOK, B.C.—The Campbell Lumber Co. are overhauling the old saw mill on the timber limits near Kitchener and expect to have it in operation by August 1st.

PRINCE ALBERT, SASK.—The Big River Lumber Co. now have, if not the largest, at least one of the most up-to-date saw-milling plants in the whole of Canada. It has been completed at a cost of $1,000,000 and stands on 150 acres of cleared ground. It is a three-band mill, with vertical and horizontal re-saw. One of the features of the plant is the planing mill, which is run by electricty generated on the ground. There are twelve boilers, each of 150 horse-power, a 1,800 horse-power engine to run the mill, and a 1,000 horse-power engine to run the dynamo which generates the electricity for the planing mill. The mill itself is fitted with all the latest devices for fire protection, including a complete sprinkling system.

COOKVILLE, N.B.—J. L. Hicks' large stationary saw mill was completely destroyed by fire recently. Loss is partially covered by insurance.

TORONTO, ONT.—W. H. Martin & Co., planing mill operators, builders, and contractors, Langley avenue, have assigned to N. L. Martin and Co., but a reorganization may be submitted to the creditors. The liabilities are estimated at $50,000, with the assets exceeding that amount.

BLAIRMORE, ALTA.—A. G. Peuchen, Toronto, has purchased Senator McLaren's saw mill, and took possession on May first.

VANCOUVER, B.C.—John Hanbury has erected here a million dollar plant, capable of turning out 1,000 doors a day. Mr. Hanbury has two large mills in the Crow's Nest country and another at Brandon.

NEW COMPANIES.

MONTREAL, QUE.—The Modern Gas, Light Heat & Power, Ltd., capital stock, $250,000, have been incorporated to manufacture and deal in gasoline and gas engines and all kinds of machinery appliances, plants and tools, etc. P. TORONTO, ONT.—The National Electric Heating Co., capital $60,000, have been incorporated to manufacture and sell electrically-heated devices and other electrical appliances. B. Enusevsky, manufacturer, A. Pritzker, electrician, S. Harris, merchant, S. Enusevsky, married woman, R. MacGregor, gentleman, C. E. A. Dowler, bank manager, and J. B. Dalzell, solicitor, all of Galt, Ont.

MONTREAL, QUE.—The Standard Steel Works, capitalized at $1,000,000, have been incorporated to carry on the business of iron masters, steel makers, steel converters, and to manufacture and deal in iron, steel, machinery, etc., etc. G. V. Cousins and O. B. McCallum, barristers, P. F. Brown, secretary, W. R. Ford, clerk, and S. T. Mains, bookkeeper, all of this city.

JOLIETTE, QUE.—The La Fonderie du Peuple, Limitee, capitalized at $40,000, have been incorporated to cast, mold and smelt metals, and carry on the business of founders, etc. H. Desmarais, machinist, J. Lafleche and U. Chaput, merchants, J. A. Guibault and E. Hebert, advocates, and A. Boucher, broker, all of this place.

TORONTO, ONT.—The British-Canadian Shipbuilding & Dock Co., capital $10,000,000, have been incorporated to design, construct, enlarge, repair, complete, etc., etc., dry docks, floating docks, etc., and to carry on the business of shipbuilding, foundrymen, iron founders, brass founders, tool makers, machinists, etc., etc. Sir Henry Pellatt, Lieut.-Gov. Gibson, both of Toronto; C. Ellis, of Cyldebank, Scotland; A. Gracie, of Glasgow, Scotland, and A. C. Ross, of Sydney, N.S.

AN INTERESTING SHIPMENT.

Electrical and mill machinery and farming implements formed a large part of the cargo of the Japanese steamship, Canada Maru, which left port recently for the Orient on her maiden voyage out from Victoria. The liners of the Osaka Shosen Kaisha line carry large shipments of machinery on every voyage out from the Sound besides much other freight.

Machinery and farming implements leaving on the Canada Maru were valued at about $100,000. There were 467 cases of electrical machinery and fixtures, valued at $30,178, and 229 pieces of mill machinery, valued at $30,420. There were 118 pieces of farming implements, valued at $20,630; 22 pieces of engine machinery, valued at $250, and five pieces of laundry machinery, valued at $433.

PLACE STEEL ORDERS.

The Canadian Car and Foundry Co. has placed an order for 50,000 tons of plain structural material with the United States Steel Products Co. Plates and shapes will be rolled at the mills of the corporation. The prospect is also favorable for further important orders for finished steel, including rails for export to the Dominion. Canadian car shops are overflowing with orders, and locomotive works, too, are well supplied, while Canadian rail mills have their full capacity sold for a year. This is a marked contrast to the lean orders that have been placed by U.S. transportation companies with domestic equipment shops, the most important of which are running only 40 per cent. of capacity.

MONSTER INDUSTRY LOCATES AT HAMILTON.

Hamilton, Ont. has succeeded in inducing the Standard Underground Cable Co., of Pittsburg, to locate there and gets what will undoubtedly prove to be one of her greatest industries. The company have already let a contract for a $100,000 building, the first of the five or six to be erected at a cost of $500,000. As a starter, they will employ 300 hands and when in full operation its staff will number about 500.

STEEL COMPANY OFFICERS.

At a meeting of the Steel Company held at Hamilton recently, the following directors were elected: C. S. Wilcox, Hamilton, president; Charles Alexander, Providence, R.I.; Hamilton Benn, London, Eng.; Lloyd Harris, M.P., Brantford; H. S. Holt, Montreal; W. D. Matthews, Toronto; Hon. Wm. Gibson, Beamsville; Cyrus A. Birge, Robert Hobson, William Southam and John Milne, Hamilton.

H. L. Peiler & Co.

H. L. Peiler & Co., agents for Canada of the Bundy trap, Mason's valves, etc., took possession on first May of new and very much larger premises at 380 St. James St., Montreal. Mr. Peiler's new office occupies the ground floor with show windows and is located in what is known in Montreal as "Machinery Row." This step has been necessitated by increasing business.

BOOK REVIEWS.

INDUSTRIAL PLANTS—By Charles Day, 294 pages, 5½x7½ ins., illustrated; published by the Engineering Magazine, 140-142 Nassau St., New York. Price $3.

As the arrangement and construction of industrial plants should be considered in scientific management, this treatise should greatly assist in bringing the plant up to a high state of efficiency and economy. In this book Mr. Day defines, in permanent form, the principles and the practical precepts of scientific plant construction. Chapters I. to VIII. inclusive of this excellent volume is founded upon a series of lectures delivered by the author before the Graduate School of Business Administration, Harvard University, and the engineering students at Columbia University. They have to do largely with the enunciation of broad industrial principles and a definition of the manner in which the arranging and planning of industrial plants should be conducted to arrive at the most satisfactory of these principles. One of these chapters is devoted to a fairly complete exposition of the use of the routing diagram as a basis of the laying out of industrial properties.

The other chapters give specific information on some of the important problems that enter directly into the metal-working plants, and particularly machine shop work. One chapter includes descriptions of the principal points of interest presented by a number of plants selected as illustrating the trend of modern practice. They exemplify results secured when the problems of planning and building are approached in a logical and thorough manner. Chapters XI. and XII. deal with the "Value of an Engineering Organization to the Project," and "Compensation for Engineering and Construction Service," respectively. This latter is of value to industrial managers as many of them are at a loss to know how to secure, for their own benefit, the economies resulting through the applications of the principles referred to in Chapters I. to XI. A copy of this book will be found of great value, therefore, to managers of industrial concerns.

ELECTRICITY EXPERIMENTALLY AND PRACTICALLY APPLIED—by Sydney Whitmore Ashe, B.S., E.E., author of "Electrical Railways," published by the D. Van Nostrand Co., 23 Murray and 27 Warren Sts., New York; 349 pages, 5½ x 7½ ins. Price $2 net. The treatise is for the beginner and for practical men dealing with electrical principles, experiments, practical applications and problems. It presents the subject from an experimental standpoint and in a very simple way showing the practical features. The volume is particularly adapted to courses of instruction given to those engaged in actual electrical work and should likewise prove useful as a text for high schools and for college laboratory courses. There are seventeen chapters arranged as follows: Magnetism, Electro-Magnetism, Electro-Magnetic Induction, Ohm's Law, Primary and Storage Batteries, Electrolysis, Three-wire System, Electrical Measurements, Shunt Motor, Series Motor, Incandescent Illuminants, Recording Wattmeters, Alternating Currents, A. C. Transformer, Induction Motor and the Rotary Converter. The subject matter is well illustrated, there being 422 illustrations used in the text.

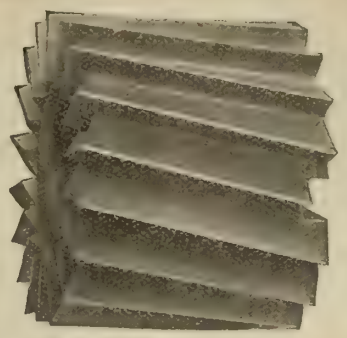
HEAT ENGINES—By John R. Allen, Professor, and Joseph A. Bursley, Assistant Professor in mechanical engineering at the University of Michigan; 288 pages, 6 x 9 ins.; illustrated; published by the McGraw-Hill Book Co., 239 West 39th St., New York. Price, $3 net.

This book treats of steam, gas, steam turbines, and their auxiliaries and is prepared as an elementary treatise on the subject of heat engines, only those which are most commonly used being considered. It was written

primarily as a text book, the subject-matter having been used in the classes at the University of Michigan for a number of years. There are eighteen chapters dealing with Heat, Elementary Thermodynamics, Properties of Steam, Calorimeters, Combustion, Boilers, Steam Engines, Steam Turbines, Gas Engines, etc. Problems are given at the end of each chapter and the book is a useful one to the student of power.

WATER TURBINE PLANT—by Jens Orten-Boving, M.I.M.E., published by Raithby, Lawrence & Co., Thanet House, 231-232 Strand, London, W.C., Eng., 197 pages, 9x11 ins., illustrated. Price, 10s. 6d.

This book has been prepared primarily as a text-book dealing with the modern theory, design, and application of water turbines and accessories, and also as a catalogue. It is confined to the more purely mechanical portions of water power installations. It is interesting to note that the basis of the volume is a series of lectures which Mr. Boving read before the Japanese Association of Mechanical Engineers of which Mr. Boving is a member The letters were eventually privately issued in book form as a part of the journals of that Society; since that time they have become a text book for students of water power and its problems, in Japan.



The work is divided into three sections (1) Theory and Tests. (2) Classification and Dimensions and (3) Description of Various Power Stations. This is very complete and of great value for the purpose for which it is written. Mr. Boving is president of the Canadian Boving Co., Toronto, who have made a number of installations in Canada. References to some of these are made in Part 3, notably among them being the plants at Winnipeg and Calgary.

ELECTRICAL POCKET BOOK—Annual Electrical Pocket Book and Diary for 1911, published by the Technical Publishing Co., 55 and 56 Chancery Lane, London, W.C., Eng., 3½ x 6 ins., 567 pages, excluding diary. Price, cloth, 1s. net; leather, 1s. 6d. net; postage, 3d. extra.

In this edition several sections have been revised and less important matters have given way to new items. The articles on the dynamo have been revised by C. C. Hawkins, M.A. Among alternations and additions which now appear are: Notes on the Ward-Leonard, Ilgner and Westinghouse rotary-converter equalizer systems; balancers and boosters; metallic filament lamps, Edison storage cells, re-arrangement of wire tables, etc.

DYNAMO ELECTRIC MACHINERY—Eighth edition, completely rewritten, dealing with Dynamo Electric Machinery; its construction, design and operation (direct current machines) by Samuel Sheldon, A.M., Ph.D.; D.Sc. professor of electrical engineering at the Polytechnic Institute of Brooklyn, and Erich Housmann, E.E., M.S., instructor in the Polytechnic Institute of Brooklyn; 5 x 7½ ins.; 328 pages, illustrated, published by the D. Van Nostrand Co., 23 Murray St., New York. Price $2.50.

The book has been written as a text book for use of students, the method of presentation being especially adapted to the classroom. With the exception of the first two chapters, the book has been entirely rewritten; nearly 200 of the illustrations are new, most of them having been especially drawn to make clear methods of construction and characteristics of operation; and it has been considerably extended in scope. In the new matter is included a set of problems at the end of each chapter, a presentation of the theory of commutation, means for the predetermination of the operating characteristics of direct current generators and mo-

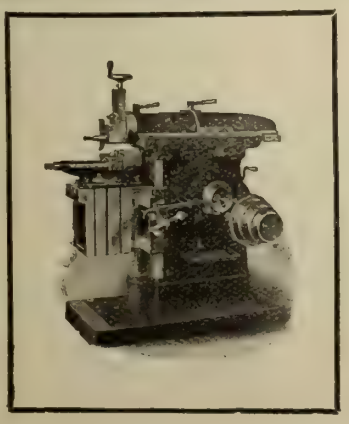
"Dart" Unions
CANNOT LEAK



Pick out the most inconvenient and meanest joint in the shop---a joint that continually causes trouble by leaking---put a Dart Union in its place and it will never bother you again.

The BRONZE TO BRONZE connections insure a perfectly tight joint, whether pipes are in or out of line.

Dart Unions have a positive guarantee. Ask your jobber for this money saver.

DART UNION CO., Limited, 93-97 Niagara St., Toronto, Can.

The Shaft Bearings in

STEPTOE SHAPERS

never wear out. They are provided with bushings that can easily be replaced if necessary, and Ring Oilers keep the bearings constantly flooded in oil, thereby preventing the shafts from getting hot and cutting. The Bull Gear Bearing has a chain oiler, and a number of other features (which we cannot explain here) make STEPTOE SHAPERS "just a little better."

The John Steptoe Shaper Co.

Agents: GENERAL SUPPLY CO. OF CANADA, Limited, Ottawa, Toronto and Winnipeg

ers a discussion on storage batteries from the engineering point of view, a treatment of the theory of balancers and of boosters, and a discussion of costs, prices and operating expenses of machines and plants. The book covers the field intended by the title thoroughly as is shown by the following chapter titles: 1 Electrical Laws and Units. 2 Magnetic Laws and Units. 3 Armatures. 4 Field Magnets. 5 Armature Reaction and Commutation. 6 Efficiency of Generators, Constant Potential Generators and Constant Current Generators. 7 Motors. 8 Dynamometers, Motor Generators, Boosters and Storage Batteries. 9 Central Station Equipment.

FEED WATER HEATER.—The Stewart Heater Co., Buffalo, N.Y., have issued a booklet of illustrative and descriptive matter pertaining to the various types of Otis tubular feed water heaters, combined with oil separator and purifier. These are made for either exhaust or live steam in vertical or horizontal form. The heater body is of steel or iron boiler plate, riveted at the top end to a heavy cast iron ring, with projecting rim cast on its outer surface, forming a flange, to which the tube sheet and top dividing plate is attached by one row of bolts. The lower end of shell is riveted to a heavy cast iron conical bottom, and which is in the case of the vertical type, supported by four legs, forming a substantial base. The tubes are of seamless brass. Prominent among the features claimed for these heaters is the facility with which they can be cleaned, the certainty of precipitation of impurities in the heater before the water enters the boilers, the absence of back pressure, the fact that each tube may expand independently of the others, the extraction of the oil, the separation of the water of condensation and means for carrying it off. With one square foot heating surface per horse-power used water at boiling point is guaranteed from exhaust steam.

VULCAN SOOT CLEANER.—A booklet received from the Vulcan Tube Cleaning Systems, Ltd., 204 St. James St., Montreal, gives testimonial letters telling "what users are saying about the Vulcan soot cleaner."

SPRAY NOZZLES.—The Buffalo Forge Co., New York, have issued a booklet describing their spray nozzles and strainers. They cover such purposes as mine washing, gas washing, condensing plants, chemical plants, etc. The text and illustrations show their construction and detail their operation.

The Moreau Pulpwood Barker

The cheapest and most economical barking device on the market to-day.

WASTE: 16 to 18% according to size of wood.

VALVE DISCS

from the wonderful new material

"BAKELITE"

"BAKELITE" has sounded the doom of valve discs of every other material, and for the following important reasons:

"BAKELITE" Discs can be used universally for cold water, wet or dry steam, superheated steam and chemicals.

"BAKELITE" Discs are made under high temperature and will, therefore, meet the conditions of high temperature service. They are affected by absolutely nothing except careless handling and friction, having great strength and hardness. They stand excessive wear and can, when necessary, be reground and refaced, always retaining a uniform surface.

"BAKELITE" Discs are a boon to valves which are constantly giving trouble owing to the use of special liquids, high pressure and high temperature—they cannot become soft.

Do not use high priced special metal discs when "Bakelite" is *better* and *costs less money.*

Order "BAKELITE" Discs from your dealer and use them anywhere in the plant. You will never use anything but "BAKELITE" Discs when you have once tested them. They mark a new era in valve efficiency.

Write us direct if your dealer hasn't them

Double Seated Noiseless Back Pressure Valve

The construction of the inner Valve and seats is of such a nature that uneven expansion of the metals will not cause the Valve to STICK or BIND—A FEATURE which places this Valve in a class by itself. ANOTHER FEATURE of our Back Pressure Valve is that it can be placed in ANY POSITION.

It is a DISTINCT improvement on the OLD STYLE single seated Valve. It has a DOUBLE PISTON TYPE of inner Valves, with disc of different area.

Guaranteed close regulation without excessive weighting. Carried in stock from 2 to 16 inches.

"Only reliable goods can be continuously advertised"

—American Machinist

New Process Noiseless Gears and Pinions have been advertised more in the last twenty years and used in greater numbers than all other makes of silent gearing combined.

Their reputation and recognition as the world's standard is based upon an absolute uniformity of quality and finish obtained only by special scientific curing of the rawhide in large lots and machining exclusively on special tools and by men whose efforts are concentrated *on this one line*.

The ability of New Process Gears and Pinions to withstand severe service is evidenced by their use as a standard part upon hundreds of the best makes of American machines. Their supremacy is further proven by use in United States Government Service, in power plants of leading commercial organizations and in every imaginable place where geared motor drive is practical.

If you have any doubts as to the performance of New Process Pinions, if you want advice on some particular installation, or if you want reference to New Process Pinions in your neighborhood, write to us. Our engineering service is free to prospective customers.

Our ELASTIC ROTARY BLOW RIVETING MACHINE forms a head as **quick as a flash,** every head nicely finished, round, square, oval, cone or flat. Runs **ten hours a day,** every day in the year.

Half a century building this Machinery proves that **we know how.**

THE F. B. SHUSTER CO., *Established 1866* ***New Haven, Conn.***

Straighteners and Cutters for squares, flats, hexagons and irregular shapes. Cotter Pin Machines, Buckle Tongue Machines, Staple Machines of all kinds. Special Automatic Machinery.

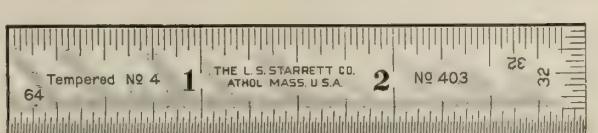
"Slocomb" Micrometers

"Absolute Accuracy" Saves Money.

An inaccurate Micrometer will waste many times its own cost by inexact measurements, causing waste of material and time.

SLOCOMB MICROMETERS are guaranteed to be absolutely accurate, being made by expert workmen who have made them exclusively for many years.

Why not buy GUARANTEED ACCURACY and save trouble in your shops?



Write for our catalog 12C and Measuring Book C. Every Machinist should have one.

J. T. Slocomb Co., Providence, R.I., U.S.A.

STARRETT TOOLS

ARE THE STANDARD FOR ACCURACY, WORKMANSHIP, DESIGN AND FINISH

THE ACME OF RULE PERFECTION

Spring Tempered Rules with heavy figures, graduated end and beveled edge. Made in 2, 3, 4, 6, 9, 12, 18 and 24-in sizes.

No. 403, No. 4 grad., with 64th's on the beveled edge, and graduated in 32nd's on opposite sides of one end.

No. 404, No. 4 grad., with 64th's on the beveled edge, and graduated in 32nd's on one side and 48th's on the other side of the same end.

These rules are the most advanced product of the rule maker's art. They are sold at the same price as ordinary spring tempered rules.

The Union Drill Chuck

has many points to recommend it. It is an accurate Chuck and all parts are strong and durable. The Jaws and Screw are made of a high grade tool steel, and are made to give long wear. In addition, the Chuck is provided with a positive drive feature, which, if properly used, will add to the life of the Chuck, and save wear of the drills. Made in seven sizes, with capacity up to 2 inch drills.

The Making of Hollow Castings

The recent introduction of King Kore Kompound has now rendered this, once somewhat difficult, part of Foundry practice comparatively easy.

It has, also, reduced the core expense by more than one-half.

This compound is a black, dry powder, and is used as flour is used, but with one-half the quantity is produced greater and better results.

Its use avoids the danger of swelling or "blowing." The core easily comes out of the casting, and when old cores are ground up, in the rattler, or otherwise, the sand so made is used over again.

The core compound it contains, again becomes a binder under heat of the core oven, as it melts, and so it is used over and over again.

This is Foundry Economy; Flour, Rosin, etc., are now luxuries.

A barrel of King Kore Kompound will be sent "subject to approval" to any inquiring mind.

That is the **Stevens' System** of trying before buying.

I have copies of proportions of compound to sand used and methods followed in core rooms of Foundries in thirteen different States. This information, with other printed matter relative to the subject, will be mailed on request.

I maintain a direct branch at 137 Jarvis St., Mr. J. M. Mayers, Manager, Toronto, Ont., where is stocked a supply of **Foundry Facings, Foundry Supplies, Buffing Compositions**, of my own manufacture.

The stamp of quality pervades them all.

FREDERIC B. STEVENS

Canadian Branch - - - 137 Jarvis Street, TORONTO.

PERFECT CASTINGS

Don't consider a casting like this to be useless—at a slight cost it can be made as good as the **best casting you ever made.**

Don't continue a needless waste. Consider what a saving there is on just one such casting as this. Then consider what a year's saving would be. Then try a can of **Shelton Metallic Filler**

No More Scrap Heap

No More Lost Profits

Shelton Metallic Filler

No More Delayed Shipments

No More Disappointed Customers

This illustration shows how a man saved the above casting from the "scrap-heap." A spatula, a little time, and a little Shelton Metallic Filler were all the requirements necessary to make it a highest quality casting.

Shelton Metallic Filler is guaranteed to fill in and completely obliterate blow holes, sand holes, etc. It becomes part of the casting itself, is durable, and can never be detected. It has been used with great success for many years. **Better write to us at once.**

FRANCIS HYDE & COMPANY

31 Wellington Street

MONTREAL, CANADA

Five years ago, the De Lamar Copper Refining Co. purchased 614 Smooth-On Corrugated Iron Gaskets, for their plant, sizes from 4 to 18 inch pipe.

They wrote us April 14, 1911, as follows:—

Gentlemen:--
Replying to your inquiry as to whether the Corrugated Iron Gaskets which we installed in 1906 in this plant have continued to give satisfaction, we are pleased to state that our steam lines have remained tight and that the gaskets have given no trouble whatever.

Yours truly
LAWRENCE ADDICKS
Superintendent

Just think, not one leak in five years. Why not use SMOOTH-ON GASKETS, and avoid leaky joints and costly repairs?

Our illustrated Catalogue is free. No engineer should be without it.

Cut from Photo

Cylindrical Grinding is One of the Supreme Tests of the Grinding Wheel, the Machine and the Man

YOU may have an expert operator behind a splendid machine, but without a wheel that cuts fast, clean and cool, and stands up to the work, neither the man nor the machine can attain the highest standard of roduction. Here is an instance where

Aloxite Grinding Wheels

are proving to be the right wheels to give the best work, the most work in the shortest time. The job is grinding 30 point crucible steel rolls 15¼ long x 2⅞ inches in diameter, with a 24 inch Aloxite wheel running 950 rpm. on a Landis grinder. .030 stock is removed and a fine commercial finish given each roll in 12 minutes.

Aloxite is the new abrasive that is making remarkable records on steel grinding. It is just hard enough--of the right degree of toughness--just sharp enough to be the ideal steel cutting material. Aloxite wheels will help your men and machines to greater efficiency and economy. Let us help you get the right wheel in the right place.

A GOLD MINE

SAVE YOUR IRON

SLY'S PATENT IRON CINDER MILL
Patented, No. 514097. Patented, No. 841728.

may be at your disposal on your very premises. Look out of your side window or back door and see if you have not an accumulation of cupola dump, and other foundry refuse, which is a total loss to you in its present state. Why not add to your profits and install one of the Sly Patent Cinder Mills to reclaim this iron and be astonished at your former loss and pocket the rich returns from your newly-discovered mine.

Sly's Patent Iron Cinder Mill will save 95% of the iron contained in your cupola dump and gangway scrapings and 75% of the coke. Iron is valuable, then why throw it in the dump? Iron recovered by this Mill is better than machinery scrap. Study economy in a foundry and your profits will increase accordingly. Mill will pay for itself three or four times every year, and we have records of Mill paying for itself twelve times a year. Let us know amount of your daily melt and we will quote. *Write for Cinder Mill Catalogue F.*

We also manufacture Cleaning Mills, Dust Arresters, Sand Blast and Foundry Equipment.

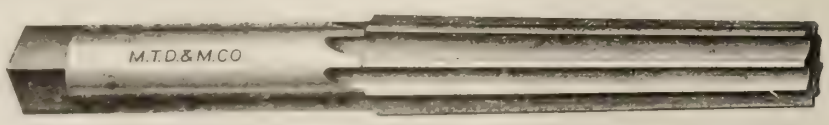
"Morse"
TWIST DRILLS
AND BRAINS



It is a "Pay Streak" for you and the manufacturer to have Brains mixed with the tools the manufacturer turns out. Brains enter liberally into "MORSE" Twist Drills. With modern mechanical development we cannot employ successfully or profitably the "Puddin' Head" element; in our plant you will find it eliminated. The work our Twist Drills, Reamers, Milling Cutters, Taps, Dies, etc., will do, is the proof. The "Puddin' Head" element is neither profitable nor desirable in your Shop.

Tools of Carbon and High Speed Steel

"PARADOX" ADJUSTABLE REAMERS

are the only adjustable reamers that have all the rigidity and accuracy of a solid tool.

"Paradox" Reamers Mean a Great Saving in Tool Expense

Consider the waste you have been subject to for years by throwing away solid reamers when the cutting edges were worn below size.

It's different with the "Paradox." They can be adjusted repeatedly to standard size until the blades are used up; then all that's necessary is a new set of blades—the body is still as good as ever.

The **"Paradox"**

Stands Unrivaled Among Adjustable Reamers in—

1st. ACCURACY. When adjusted, the blades remain absolutely parallel, insuring straight, true holes.

2nd. SOLIDITY. The blades are held securely in place, wedged in and down against the back and bottom of their grooves by special taper headed screws.

3rd. SERVICE. One "Paradox" Reamer will outlive eight or ten solid reamers before the first set of blades is worn out.

Catalog No. 33-C gives full information and list prices.

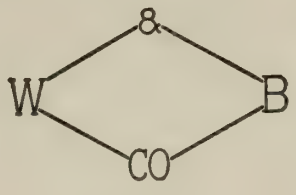
ACCURACY

To make Twist Drills that will do absolutely accurate work requires the greatest skill—years of experience and the most careful attention to each detail of manufacture.

To secure the greatest wearing quality requires the best of steel, tempered to exactly the correct degree of hardness. Not all Twist Drills attain these two essentials, but



"W & B-DIAMOND"

Twist Drills do and we ***guarantee*** them to be of ***highest quality*** and ***accurate to size.***

We make them from Carbon Steel and Vanadium High Speed Steel and carry the largest stock in Canada.

The "Hercules" High Speed Twist Drill shown on this page is one of our many types and is ***twisted*** while hot from Vanadium High Speed Steel.

TWENTIETH CENTURY MACHINE SHOP PRACTICE

by L. E. Brookes

This book is intended for the practical instruction of machinists, engineers and others who are interested in the use and operation of the machinery and machine tools in a modern machine shop $2.00

PRACTICAL MECHANICAL DRAWING AND MACHINE DESIGN SELF TAUGHT

by Chas. Westinghouse

A complete self instructor on drafting tools, geometrical drawing, mensuration, of plane surface and volume and surface of solids, the development of curves, surfaces, etc. A large section is devoted to machine drawing, including boiler and tank work, engine pillow blocks, pulleys, gear wheel designs, etc. $2.00

PATTERN MAKING AND FOUNDRY PRACTICE

by L. H. Hand

The making of castings is clearly described, the tools used by pattern-makers described and illustrated, and instructions regarding their use are given, and the process of making patterns is then taken up $1.50

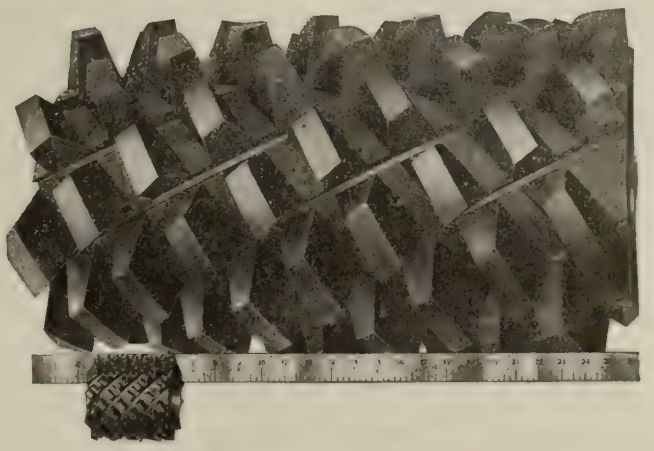
143 UNIVERSITY AVENUE, TORNOTO

That's the Stuff.

LAFFITTE WELDING PLATES



Will save you more on a single difficult job than they will cost you for a year. If you use them encourage their use. If you don't, get busy--you are losing opportunity. SAMPLES FREE

THE PHILLIPS-LAFFITTE CO.

Penna. Bldg. Philadelphia, Pa.

We Make Accurate Hobs

WORM GEAR HOBS

SPUR GEAR HOBS

The manufacture of accurate hobs is a difficult task and cannot be accomplished by the aid of special facilities alone. Long experience, together with specially designed machines for cutting and relieving the hobs, are a necessity. So, also, are special machines needed for grinding, but when it comes to the hardening, no rules can be given. Here experience counts, for each hob must be treated differently, according to the size, hole, length, etc. *We have made hobs for more than 20 years.*

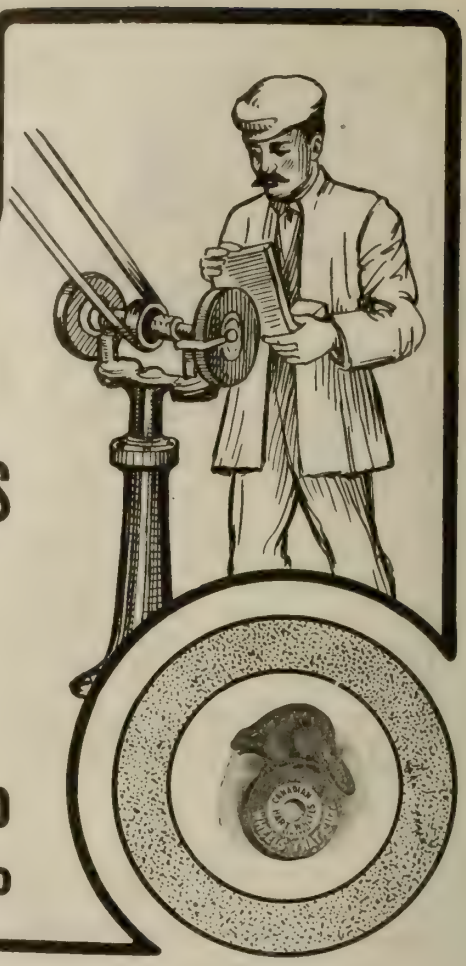
FIRE BRICK
for
Cupolas

¶ The standard Fire Clays by which all other Clays are judged are those of Pennsylvania.

¶ They're the ones from which our Cupola Brick are made.

¶ The cost per thousand means nothing unless you know the results the Brick are giving.



¶ Write us for definite examples of how our material affects your melting costs.

HARBISON-WALKER REFRACTORIES COMPANY,

PITTSBURGH, PENNSYLVANIA

The Daily Grind

The daily grind of mechanics engaged in using abrasive wheels is made much more effective if their machines are fitted with

CANADIAN HART CORUNDUM WHEELS

Our wheels are free and fast cutting, porous, safe, and very durable. Send for our catalogue which describes the various processes used in making Canadian Hart Corundum and Emery Wheels.

If You Are Now Having Trouble Getting Your Work Out On Time---If You Are Rushed---If You Would Assure Accurate Work---Study This New Gap Lathe---Get One And See Your Troubles End

DESCRIPTION

Headstock construction prevents chattering, and deep oil chambers fitted with ring oilers make spindles and bearings self-oiling and always well lubricated.

Tailstock of a special type, and sleeve is clamped by a quick acting locking device. Tailstock is secured to bed by bolts adjusted from the top where they are easily accessible.

Bed, non-springing and webbed, and braced to secure rigidity.

Gap, vibration absolutely prevented by use of brace supports to carriage.

Spindle, high carbon hammered steel in solid chilled cast iron bearings, accurately fitted and self oiling.

Carriage and Apron, non-springing under severest strain, full "V" bearings and flat bearings in addition on front ways.

Double Back Gears give eighteen distinct spindle speeds, suiting lathe to work on widely different diameters

Compound Rest, with graduated base, accurately fitted taper gibs, end adjusted. Screws in both rest and cross slide read to thousandths.

Friction, Safety Feeds, screw and rod feeds cannot be both engaged at the same time. Quick changes of 1¼, 2½ and 5 times thread being cut.

Gears and Racks, cut from solid and steel where necessary.

Screw Cutting, full range of commercial threads provided for.

Equipment, Compound rest, steady rest, follow rest, large and small face plates, wrenches, two-speed, friction countershaft furnished with each lathe.

Accuracy, Strength, Solidity, Wear. These are the paramount features behind all McDougall Machines. Made **to meet extreme demands.**

STANDARD TOOL CO.

Westinghouse Type "SA" Motor Driving Slotter

To secure fine adjustments of speed in the operation of your lathes, shapers, boring mills, drill presses, etc., drive them with

Westinghouse
Adjustable-Speed Motors

With an adjustable-speed motor mounted on the machine full and positive power is assured at all times and at all speeds.

The speed adjustments are made through a comparatively small and compact controller within easy reach of the operator. In lathe driving a splined shaft may be run along the bed and the controller operated from the tool carriage, making the speed adjustment as convenient as the feed adjustment.

The controllers are designed so that the speed increments are in steps of 12 to 15 per cent. or less if required, as compared with the 40 to 50 per cent. speed increments in the usual cone-pulley arrangement of mechanical drive with belts. Section 7 of our Catalogue 3002-A illustrates many tools driven by Westinghouse Motors.

WINNIPEG, 158 Portage Ave. East. CALGARY, 311 8th Ave. West. VANCOUVER, 439 Pender Street.

Cost Reducing Features

An indestructible spindle bearing made of hardened steel and cast iron.

A head construction that gives more effective pulling power at the spindle than any other lathe built.

A patent "oompensating V" that permits four times the bearing area between the carriage and bed found on other lathes.

A carriage in which the tool thrust is taken on a bearing the entire length of the carriage, and which positively will not climb the V.

A double-walled one-piece apron which will last as long as the rest of the lathe.

A quick change gear complete in one unit, giving thirty-six changes with two operating levers.

An offset compound rest which can be used without skinning the operator's knuckles.

The centres set back of the middle of the bed, giving greater swing over carriage and permitting the turning of work up to the maximum swing without the tool overhanging the bed.

Do YOUR Milling the Cincinnati Way

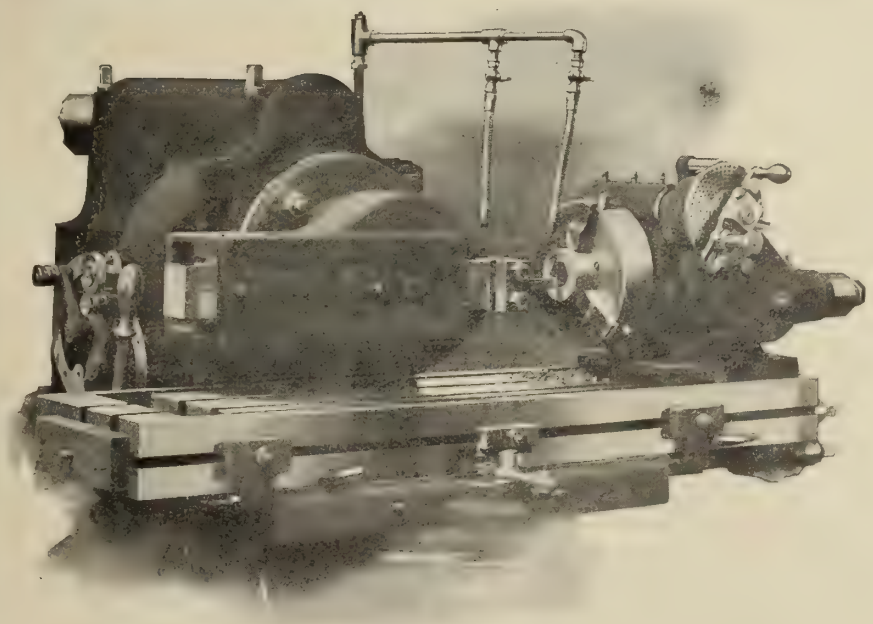
526

THIS operation roughs out the inside of Cast Iron Vise Bodies. Total width of cut 15 inches; greatest depth 3-16 inch; length 6 inches. The largest cutter is 6 inches in diameter, 9 3-8 inches face, runs 32 revolutions, feeding 4 3-4 inches per minute.

The pieces are held in a string jig—each one clamped independently. The milled pieces are removed as fast as traversed by the cutter and others chucked in their places.

At the end of the cut the knee is lowered, the table returned, readjusted and a new cut started.

The operator then removes the last piece at the right-hand end of the jig and chucks a new one.



By this time the first one at the left has been milled and he repeats the above process by again chucking new pieces behind the cutter.

Both the operator and the machine are busy all the time. Neither waits for the other. The only time lost is returning and readjusting the table, and the TOTAL TIME PER PIECE IS ONLY 4 1-4 MINUTES. Let us show you how to mill your work the Cincinnati way.

The Cincinnati Milling Machine Company

CINCINNATI, OHIO, U.S.A.

Canadian Agents—H. W. PETRIE, Toronto, Montreal and Vancouver

The Most Intricate Scroll Work

No. 50 HIGH DUTY BAND SCROLL SAW
Equipped with Modern Safety Doors

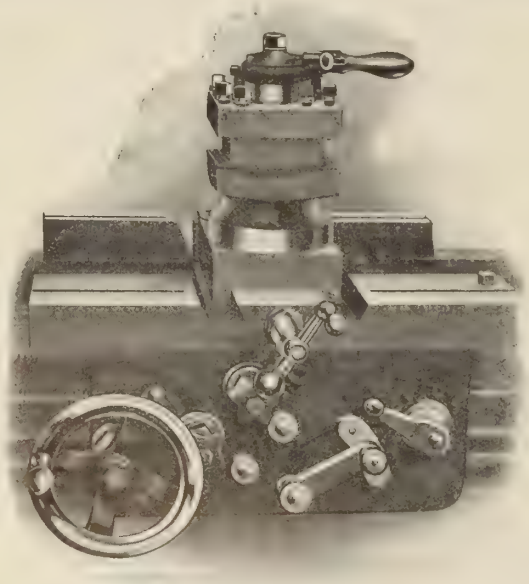
can EASILY and QUICKLY be done on our

No. 50 HIGH DUTY BAND SCROLL SAW

To give you an idea of the superiority of this **High Duty Band Scroll Saw,** we publish below the contents of a letter received from a prominent manufacturer, whose name we will gladly send you if you desire.

"Some time ago I noticed one of your No. 50 Band Scroll Saws at work in another factory, and it appeared to work so nicely that the next time I needed a Band Saw, I decided to try one of yours, even though it was just about 50% higher than I had been paying for this class of machine.

I got such excellent results from it that I have since purchased eight machines. I am now using nine of your No. 50 Band Scroll Saws and am well pleased with the results I am getting from them."



This machine is equipped with our Patent Knife-Edge Straining Device which allows the use of the thinnest blade possible—enabling the machine to turn out **high quality of work at a lower cost of production** than any other Band Scroll Saw on the market. This is only one of the many exclusive features entering into the construction of this machine. You ought to know more about it.

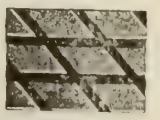
LAFFITTE



The New French Brazing Compound

No. 1
For Brazing Brass, Red Copper & Bronze

No. 2
For Brazing Red Copper and Iron

No. 3
For Brazing Iron and Steel

These three contain all the necessary ingredients for a perfect braze, including a great proportion of copper solder.
As they melt at different heats it enables the brazier to have a solder which fuses at a lower heat than the metal being brazed.
Does quicker, cleaner, better work. No swelling or blistering.
Leaves braze free from oxides and residue ready to finish.

SAMPLES FREE on request.

ONE HOUR'S WORK

WITH AN ELECTRIC WELDING MACHINE

Sixty minutes' work and over a thousand in this pile (Count 'em.)

THE BOY IS WELDING STEEL HOOPS FOR BARRELS

He places a hoop in the welder—the jaws come down and clamp the stock, the circuit is closed—the weld completed—the circuit breaker opens—the wire is released—all done automatically. Time: 3 seconds or 20 per minute.

It's a power driven machine requiring about half a horse power to run it. The speed can be varied from 15 to 30 welds per minute depending on size of stock. Can be used for a great variety of small work where it's the quantity that counts.

Figure the cost:	Current at 5c. per K.W. hour for 1,000 welds	.10
	Boy's time at 20c. per 1,000 welds -	.20
	Total for 1,000 welds - - -	.30

Ten thousand pieces per day at a cost of three dollars

This is only one of nearly fifty different kinds and styles of welders we make and if we haven't got what you need for your work—we'll make it. That's our specialty—building welding machines: good ones, of course, or we wouldn't be the largest manufacturers of welding machines in the country to-day.

By the way, our new bulletin is a text book on Spot Welding, or riveting without rivets, and it's yours for the asking.

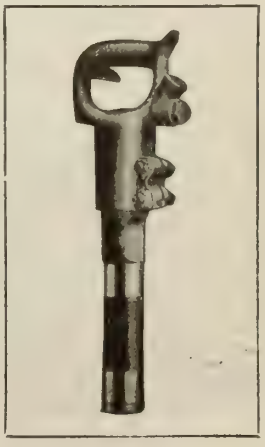
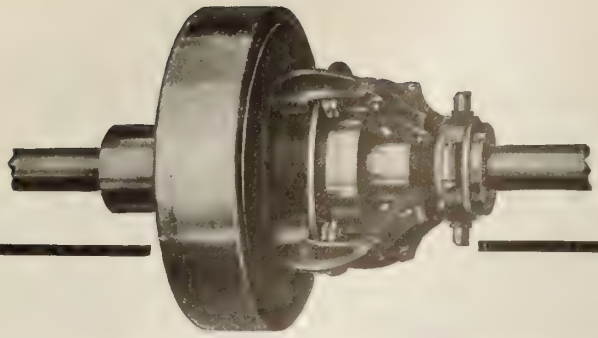
PNEUMATIC TOOLS



The absolute safety and simplicity of transmitting compressed air, its wide range of profitable uses and the economies effected by its uses, give it an indisputable position of supremacy as a means of transmitting power for operating small portable tools.

Pneumatic tools are not delicate, complicated pieces of machinery, but positively simple, rugged little money savers, made to stand rough usage, yet maintain their efficiency.

In "Imperial" designs wearing parts are reduced to the reasonable limit of simplicity, and manufactured to give the greatest satisfaction.



No part of a plant equipment, representing the same investment, will do more to reduce labor costs, increase output and enlarge dividends than a good pneumatic tool equipment. We firmly believe that "Imperial" tools represent the very best sustained value, first costs, maintenance and operating costs being considered. They are thoroughly well designed, embody all practical up-to-date improvements and give very exceptional efficiencies. These features have won for "Imperial" tools their present favored position.

THE SAFEGUARD

If, because of several recent burglaries in your neighborhood, you had decided to install burglar alarms on your doors and windows, you wouldn't put them on all the windows but one, and that one a back window in a secluded nook where thieves might be most apt to break in and steal your money. Why should you make the same mistake in buying clutches?

Your primary reason for purchasing clutches is to safeguard your power—your money—to shut off idle machines or groups of machines and prevent them from robbing you. But there is that "back window in the secluded nook" where, if you only knew it, more of your power can be appropriated than the saving in control can offset—and that is while driving with ordinary slipping friction clutches.

There is but one clutch that absolutely safeguards all your power—your money—the POSITIVE Combined Jaw and Friction Clutch. The Jaws do the work and they are positive. Therein lies The SAFEGUARD.

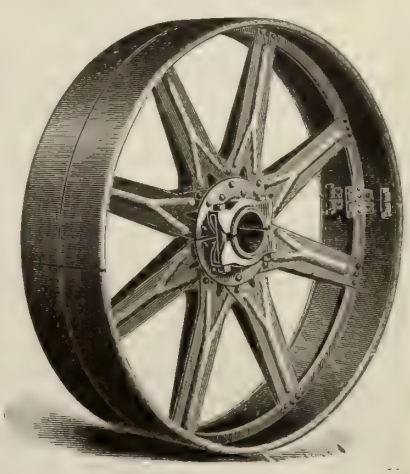
"GENERAL SUPPLY SERVICE"

IS QUICK AND EFFICIENT

When you are in the market for equipment or supplies of any kind you naturally want to buy where you can feel sure of having your requirements filled with the least possible delay, and with goods backed by a manufacturer with a reputation to maintain.

Some of Our Lines



Among the prominent firms we represent are the following:—

London Machine Tool Co., Machine Tools.
John Steptoe Shaper Co., Shapers.
R. K. LeBlond Co., Milling Machines, Grinders & Lathes.
Fay & Scott, Lathes.
Mueller Machine Tool Co., Radial Drills.
H. G. Barr, Sensitive Drills.
Cleveland Twist Drill Co.
South Bend Machine Tool Co., Lathes.
Hisey-Wolf Machine Co., Electric Drills.
American Pulley Co., Pressed Steel Pulleys.
Standard Pressed Steel Co., Steel Hangers.
Beardmore Belting Co., Leather Belting.
Vi-Balata Belting.

Besides our general line of Mill Supplies, Contractors' Plant and Supplies, Transmission Equipment, etc., we have recently added a list of first class Machine Tool agencies, and have engaged special salesmen to look after this department, who have made this line their special study for years.

When you are in the market for machine tools it will pay you to let us quote.

We have a large stock of "AMERICAN" Steel Split Pulleys in our warehouse. Come in and see them. Made in sizes 6 to 60 ins. diameter and 2 to 36 ins. face. Also large stock of Pressed Steel Hangers.

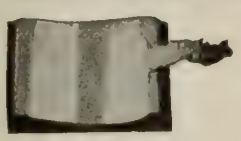
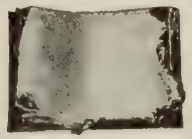
MAGNOLIA METAL - vs - "GENUINE" BABBITT



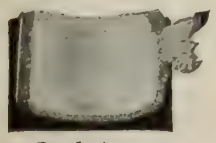
MAGNOLIA TEST BLOCK:

Ran 80 minutes under pressures varying from 1000 to 2000 lbs. per square inch, 1600 revolutions per minute; in perfect condition at end of test with smooth highly polished surface.

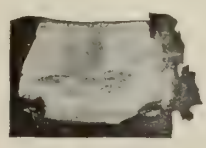
"GENUINE" BABBITT TEST BLOCKS:



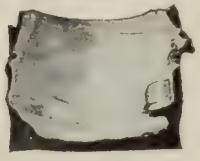
The best grades of "Genuine" Babbitt were selected for these tests.



Ran 15 minutes, 1,000 lbs. square inch



Ran 30 minutes, 500 lbs. square inch



Ran 15 minutes, 1,000 lbs. square inch

Ran 5 minutes, 1,000 lbs. square inch

Ran 10 minutes, 1,400 lbs. Souare inch

Ran 10 minutes, 1,200 lbs. square inch

We tested six other "Genuines" which were all similar to above.

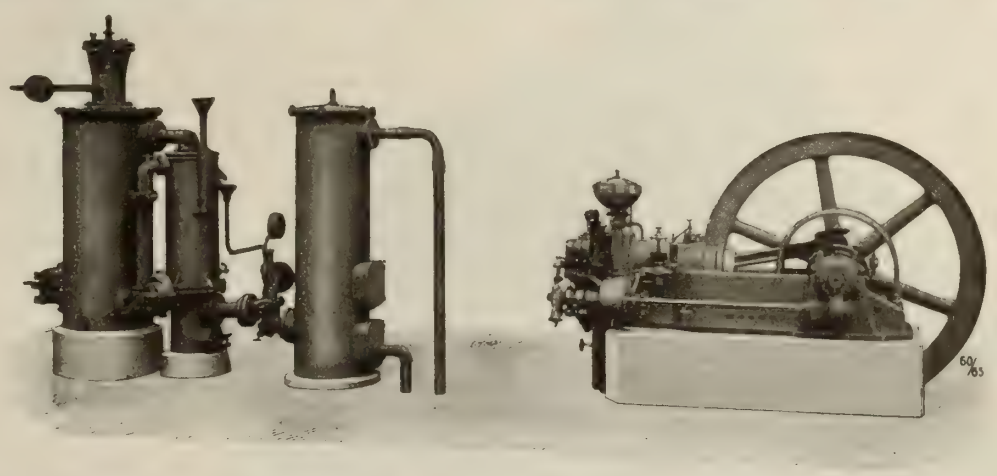
Special Offer

PRACTICAL ENGINEER POCKET BOOK, 680 pages, over 2,000 subjects. We do not aim to make a profit on this book as it is an advertisement, therefore offer it at the very low price of 40c. postpaid Many Engineers pronounce it invaluable. Address Montreal Office.

Showing the Superiority of Magnolia over "Genuine"

The tests shown hereon domonstrate our claim that a tin base metal is highly susceptible to friction heat and therefore liable to squash, and that it is almost impossible to raise the temperature of a Magnolia-lined bearing to a destructive point; hence the secret of its wonderful success.

Some day we will show you where a Magnolia-lined bearing is running in shafting and **has been running for six years without one drop of lubrication.**



These tests were made by Dr. Torrey, who was then Chief Assayer of the U.S. Mint, New York

OILDAG

(Registered Trade Mark)
Deflocculated Acheson-Graphite, Dag and Oil.

Graphite does not dissolve in any liquid or break under pressure, and these qualities, added to the unctious softness and purity, together with its non-coalescing nature, make Acheson-graphite ideal for lubrication purposes.

The process of deflocculation takes Acheson-graphite powder so fine that 99% of it will go through a sieve having 40,000 meshes per square inch, and sub-divides each grain of this finest powder into many still smaller particles—so small that they cannot be seen through a strong microscope.

Oildag is this deflocculated Acheson-graphite suspended in oil, where it neither floats or sinks, but is evenly distributed throughout. Oildag will flow anywhere the oil alone will go.

Mr. Robert A. Ross, E.E., of Ross & Holgate, Consulting and Supervising Engineers, Montreal, writes:

"As my firm are constructing and operating steam plants, we have wished to use a mixture of graphite and oil for cylinder lubrication, but have been prevented by the fact that the graphite settled out of the mixture. **This difficulty you have overcome,** and we are now assured of the best lubrication in the world, especially in superheated steam practice."

Write for Oildag Booklet 77D.

Developments in the Electric Smelting of Iron and Steel

By Thos. D. Robertson, M. Met.

The Writer Gives an Interesting and Instructive Account of the Rapid Progress Being Made in the Electric Smelting of Iron and Steel, and From Figures and Data Secured From Carefully-made Tests of Operation, Shows This Process to be Commercially Valuable and of Extreme Importance to Such a Country as Canada, With its Immense Mineral and Water-power Resources.

EXPERIMENTS were made, under the Dominion Government supervision, at Sault Ste. Marie, Ont., in the winter of 1905-6 to test the feasibility of smelting Canadian iron ores, using charcoal as a reducing agent. While these preliminary investigations were regarded as satisfactory, no further experimentation was proceeded with in Canada.

Experiments in Sweden.

In Sweden, however, where the conditions governing the iron industry are similar to those in several provinces of the Dominion of Canada, the question of electric iron smelting was taken up in 1906. Three Swedish engineers, Messrs. Gronwall, Lindblad and Stalhane, commenced experiments, and after overcoming many preliminary difficulties, succeeded in the summer of 1908 in constructing a furnace which was durable and gave a good output. Profiting by experience, they determined to build a furnace of 700 h.p. at Domnarfvet, in order to test the commercial feasibility of the equipment. The experiments with this furnace were witnessed by Dr. Eugene Haanel, of the Government Department of Mines, Ottawa, and in 1909 a report was issued giving the results.

So impressed were the Swedish ironmasters with the working of this small Gronwall reduction furnace, that the Swedish Association of Ironmasters, "Jern Kontoret," determined to erect a furnace of 2,500 h.p. at Trollhattan; their idea being to thoroughly test the furnace on a commercial scale.

Furnace Test.

This furnace was started in November, 1910. Various consignments of ore were sent from the different mines of Sweden to be smelted. Most of the pig iron produced was sent to different steel works and made into steel: the quality of which was then tested.

The fuel used was charcoal, and a special store with belt conveyors and rope-way to the furnace top was built. A separate crusher house for the ore and limestone communicates by an inclined track with the furnace top. Power was supplied from the Swedish Government power station at Trollhattan, at a tension of 10,000 volts. This three-phase supply is transformed by means of two transformers of 1,100 K. V.A. each, with Scott's connections to two-phase current, which can be regulated between 50 and 90 volts.

Furnace Detail.

The height of the furnace from the ground to the charging platform is 45 feet. Two separate portions are to be distinguished; the shaft and the crucible or hearth, Fig. 1. The shaft is a cylindrical steel shell lined with fire brick, and fastened to an octagonal supporting ring, which bears on two built up beams, supported by the walls of the building. By this means the weight of the shaft and a large portion of the charge is carried, relieving the hearth roof of the weight. At the top of the shaft is a Tholander charging bell operated by a small motor; the object of this special bell being to deposit the ore and limestone round the walls of the shaft, and the charcoal in the centre.

The hearth resting on a concrete foundation, has a steel shell lined with firebrick, and an inner lining of magnesite brick. The basin shaped bottom is lined with a mixture of magnesite and tar, extending nearly to the top of the walls. The roof is of firebrick, and has openings to admit the electrodes. These latter are four in number, and pass through the roof at an angle of 65 degrees to the horizontal.

Electrode Adaption.

For the first six months this furnace ran with square, built up electrodes. Owing, however, to rapid development in the manufacture of large carbon electrodes, it has now become possible to obtain a round type of high electrical conductivity, 600 m.m. diameter. These have therefore been fitted to the Troll-

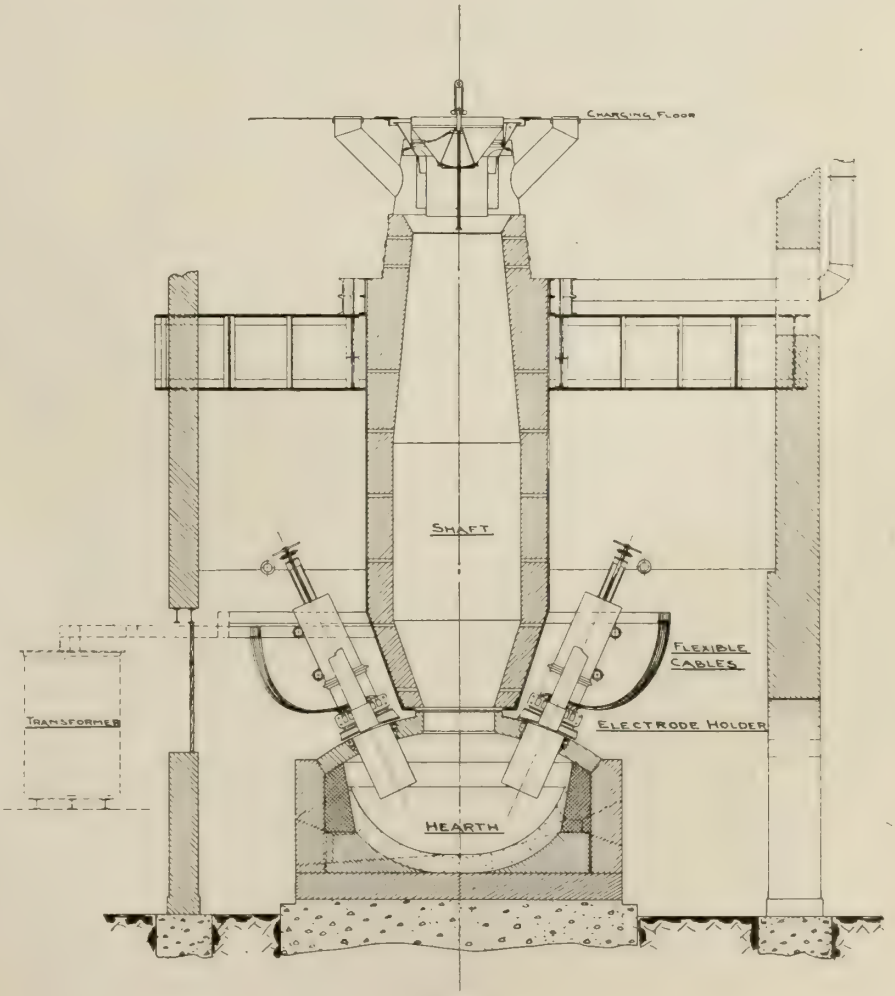

FIG. 1.

hattan furnace. The electrode holder was formerly at the top, but new holders are now fitted which grip the electrode at the point where it enters the roof. This reduces the electrical resistance losses to a minimum. Each electrode holder is supported on a frame which can be raised or lowered between two guides, by means of two long screws turned by a hand wheel. The round electrodes are fitted with screw joints, enabling a new one to be screwed on to the stump of the old, thereby doing away with waste from stump ends. Copper water jackets surround the electrodes at the point where they enter the roof.

Gas Circulation.

A novel feature of the furnace, is the circulation of the gas produced by the reduction. The cool gas from the top of the shaft is taken and blown by means of a fan through tuyeres under the roof of the hearth. This gas cools the roof and prolongs its life, at the same time becoming itself heated. It passes again up the shaft, and parts with its heat to the descending charge, thereby assisting materially in the reduction. The excess gas at present is allowed to turn into the air.

Dust catchers were used at first for cleaning the gas, but now a water scrubber has been installed, the arrangement of which can be clearly seen in the accompanying cut, Fig. 2.

General Features.

The low tension copper busbars are carried to the furnace by suspended insulated holders and the current is taken from the bars to the electrodes by means of flexible bare copper cables. The furnace is equipped with all necessary measuring instruments for temperature, pressure and gas analysis, and the instrument board has a complete set of electrical meters.

The smooth working of this furnace has been a feature from the very beginning. In most electric furnaces, the current is regulated by raising and lowering the electrodes, but in reduction furnaces working with gas pressure inside, this method is not practicable. In fact the electrodes are only lowered to adjust their wearing, this having only to be done about once every fortnight. The current is regulated by altering the primary windings of the transformers, and the arrangements are such, that the two phases can work simultaneously with different tensions.

The burden of the furnace was constantly altered during the first six months' working in order to obtain as much information as possible about its operation under varying conditions.

Large proportions of finely divided concentrates were at times used. As much as 65 per cent. caused no inconvenience in working. The shaft of this Trollhattan furnace is somewhat narrow, but with a wider shaft, it is expected that charges of all kinds will be smelted successfully.

Operation Statistics.

The following figures are averages for five months working from November, 1910 to April 1911 :—

Percentage of iron in ore ..	61.54
Percentage of iron in charge	57.00
Slag per metric ton of iron..	719.4 lbs.
Charcoal per metric ton of iron	793 lbs.
Time of working	3,348 hrs.
Time consumed in interruptions	153 hrs.
Total time	3,501 hrs.
Average load in K.W.	1,344
Total K.W.H. used	4,500,596
Iron per K. W. year (metric tons)	3.66
Consumption of electrodes per ton of iron	11.59

The gas produced is very rich, containing over 80 per cent. combustible. It was allowed to burn into the air at this plant, but arrangements are being made for its utilization in the various new plants being erected.

Steel Produced from Electric Pig Iron.

Most of the iron produced during the above period, was sent to various Swedish works and converted into steel in open hearth furnaces. These were both acid and basic, and tests on the steels produced, show them to be equal and in some cases superior to steels made from charcoal pig iron from the same ore. An interesting feature is, that low carbon pig iron made in the electric furnace can be successfully made into high quality steel in the open hearth furnace, with a considerable saving of time over ordinary pig iron. The Trollhattan furnace has used only charcoal as fuel, but four furnaces have been built in Norway which are working with coke. The coke furnace has a shaft with a smaller volume, greater diameter and less height than a charcoal furnace.

Gronwall Reduction Furnaces Working or in Course of Erection.

	E.H.P.
Sweden: Trollhattan (altered)	3,000
Domnarfvet, one furnace	4,000
Hagfors, two furnaces (3,000 H.P. each)	6,000
Norway: Tyssedahl, Hardanger two furnaces (3,500 H.P. each)	7,000
Arenal, two furnaces (2,500 H.P.)	5,000
	25,000

With the exception of Trollhattan, all the furnaces use 3 phase current and have six electrodes. Owing to the larger and better electrodes now obtainable, the writer is informed that it will now be possible to construct units up to 6,000 h.p.

Advantages of Electric Smelting.

One-third of the fuel required per ton of pig iron made in a blast furnace is used in the electric furnace, consequently only about two-thirds of the quantity of materials need to be handled. The pig iron produced is very regular in composition, as variations in the conditions due to temperature and humidity of the blast, and which cause trouble in blast furnace practice, are entirely eliminated. Owing to the basic lining of the furnace, very basic slag can be used, giving iron with low sul-

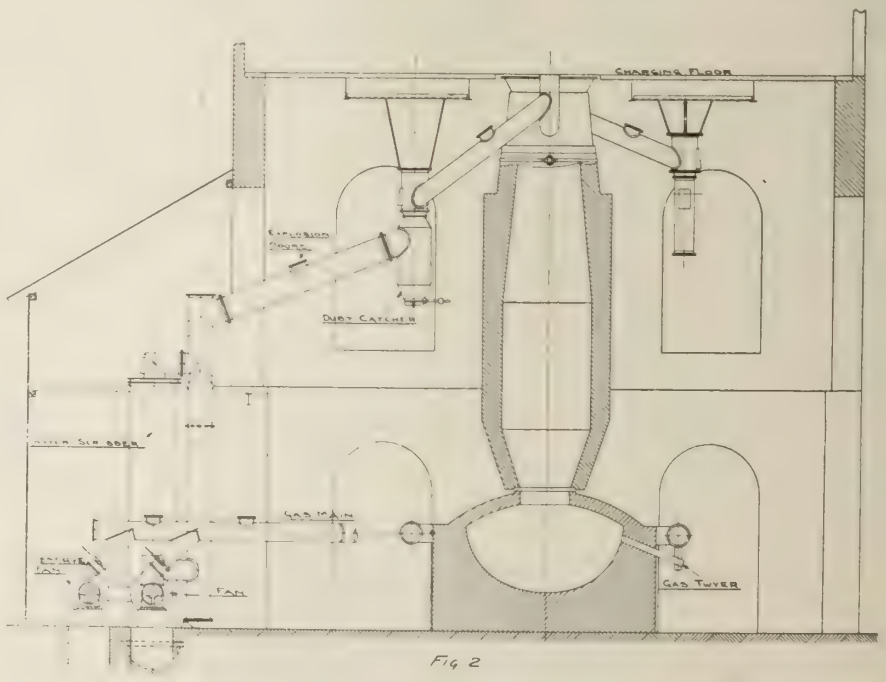

Fig 2

phur content. In fact ores high in sulphur can be smelted successfully, and which could not possibly produce marketable iron in a blast furnace. The electric furnace can smelt fine ores or concentrates without the expense of modulising or briquetting.

Cost of Production.

This varies in different localities. To make 3 tons of pig iron the electric furnace uses 1 ton of fuel (coke or charcoal) and rather less than 1 e.h.p. year. In the blast furnace, 3 tons of fuel are used to make 3 tons of pig iron.

The electric furnace, therefore, substitutes one e.h.p. year for two tons of fuel.

There are many localities having water power awaiting development, with iron ore close at hand. To many of these the freight costs for importing fuel make blast furnaces too costly, and into such places the electric furnace will come as the best apparatus for the profitable production of pig iron. It may be that it will be found better to convert the electric pig iron into high quality steel, rather than put it on the market as "charcoal" quality iron. This can very conveniently be done at the same plant. A large gas-fired metal mixer would be installed to take the molten iron from the shaft furnaces. It would be heated by the waste gas, which is very rich, and a considerable amount of refining would be performed in this mixer. The partially refined metal would then be poured into steel refining furnaces and treated so as to produce high quality steel of any desired composition.

Much progress has been made in the design of electric steel furnaces during the last few years, and one of the latest types of furnace to be introduced is the invention of the same three Swedish engineers, Messrs. Gronwall, Lindblad & Stalhane.

This furnace combines the advantage of most of the pioneer types, at the same time eliminating most of their weak points.

The Gronwall Steel Refining Furnace.

The main feature of this furnace is that it employs two phase current, and can utilize existing power supplies through static transformers, obviating the costly running plant necessary to transform three phase current for single phase furnaces.

Owing to the two phase arrangement of two electrodes carrying separate phases above the bath, and a neutral return embedded below the basic lining, the charge of molten metal is kept in gentle motion and the time for refining is reduced to a minimum. The reducing conditions which prevail at the end of the refining, produce a steel which is very sound when poured into ingots. From common raw material steel can be made of great chemical purity in a very short time. A Gronwall steel furnace, working in Sheffield, England, has produced tool steel by melting and refining old rail ends. This steel has been tested, and found equal to crucible cast steel, selling at $175 per ton. Using fluid metal as suggested above, a large output can be obtained, and with cheap power, the costs for refining would work out very small indeed.

In Sweden, some of the older firms, who have their reputations to consider, are pulling down their old plant and putting in electric furnaces. This they have done only after careful consideration, being naturally somewhat conservative. In Canada, there are ore deposits as yet untouched, there is water power awaiting development, and the demand for iron and steel in this growing country becomes greater every day. The days when electric smelting was in the experimental stage are over, and for Canada this question becomes one of national importance.

The Canadian Boving Co., 164 Bay street, Toronto, are the representatives of the foregoing equipment for the Dominion of Canada.

Success in Training Industrial Foremen*

By Charles F. Park **

The Writer Shows The Necessity There Exists for Greater Attention Being Paid to the Training of Industrial Foremen, and by Citing the Success of the Lowell Institute Course in This Field, Makes Clear That There is Not Only Necessity but Demand and Assured Success Awaiting Other Schools Who Care to Take it up.

WE are beginning to feel, that with all our efficient machinery and modern methods of manufacture, the absence of systematic training is placing our industries in a serious situation, and it has been stated, that "to-day we are reaping the sorry harvest of neglect." This condition is not only most unfortunate for the industries, but it is also deplorably unfortunate for the workmen.

Industrial Education Necessary.

What reason is there to expect that our untrained workmen will ever exercise any initiative, or that they can ever become leaders, even in a small way? How can they ever progress even from the smaller things to the larger ones, or how can they ever become qualified for positions of responsibility such as foremen, superintendents or shop managers? To be sure many men have developed under these conditions, but not because their work gave them proper training, but because they were naturally superior men. My appeal in this paper is for training that will develop the superior man, but I appreciate that there is also urgent need of industrial training for the great mass of ordinary workmen.

The superior man cannot get the desired training in the shop, and the lack of men able to carry small responsibilities or to fill the positions of greater responsibility, comes from the lack of training of the workmen themselves, and from whom we must select the leaders. Sound industrial education has seemed to several philanthropists to be the remedy.

A number of years ago Dr. Abbott Lawrence Lowell, the trustee of the Lowell Institute, foresaw the value of such training, and in 1903 he made a change in the work done by the Lowell Institute in connection with the Institute of Technology. The purpose underlying this change, as stated in an early announcement, is as follows:

Industrial Efficiency Dependent on Foremen.

We have heard a great deal in late years, of captains of industry; but the efficiency of the industrial art depends, in a very large measure, and probably to a constantly increasing extent, upon the capacity of its non-commissioned officers—in other words, upon the foremen. These men receive the same education to-day as the ordinary mechanic, and it has been thought that it would be a great benefit to the community at large if they could have some instruction in the principles of applied science, so that they might understand more thoroughly the work they are superintending, and be ready to apply improvements. It is felt, also, that a better educated class of foremen would be a benefit to the community socially, as an intermediary class between the employer or engineer on the one hand and the workmen on the other. To attempt, however, to train young men separately for the po-

* Abstract of paper presented before the Congress of Technology, at the fiftieth anniversary of the granting of the charter of the Massachusetts Institute of Technology.

** Associate Professor of Mechanical Engineering, Massachusetts Institute of Technology; Director of Lowell Institute School for Industrial Foremen, Boston.

sition of foremen would be under the existing organization of labor an impossibility. The foremen must continue, for the present at least, to be promoted from among the workmen. In giving them such an education as is desired, therefore, it is necessary to take men who are already working at their trade; necessary instruction can be given to them only in the evening.

School for Industrial Foremen.

With this object in view, it was decided to substitute for the advanced courses hitherto given by the Lowell Institute under the auspices of the Institute of Technology, an evening "School for Industrial Foremen," open free of charge, to young men who are ambitious and well-fitted to profit by the instruction. The term foremen is used in its broad meaning.

The school comprises two courses, one mechanical and the other electrical, and each extends over two years. The work of the school at the outset was practically the same as it is to-day. The courses are intended to bring the systematic study of applied science within the reach of young men who are following industrial pursuits, and who desire to fit themselves for higher positions, but are unable to attend courses during the day.

The schedule of courses is as follows, being for the mechanical and electrical, alike for the first year:

FIRST YEAR COURSE.

	Hours.
Mathematics	56
Physics	33
Electricity	28
Mechanism	34
Drawing	40
Total	192

SECOND YEAR MECHANICAL.

	Hours.
Elements of Thermodynamics, the Steam Engine and Boilers	38
Valve Gears	10
Applied Mechanics	38
Elementary Hydraulics	10
Testing Laboratory (Resistance of Materials)	12
Steam and Hydraulic Laboratory	24
Mechanism Design	12
Elementary Machine Design	60
Total	204

SECOND YEAR ELECTRICAL.

	Hours.
Elements of Thermodynamics, The Steam Engine and Boilers	38
Valve Gears	10
Steam Laboratory	16
Direct Current Machinery	12
Alternating Currents	22
Electric Distribution	30
Electrical Testing Laboratory	24
Laboratory of Dynamo Electric Machinery	48
Total	200

Evening Tuition and Work Undertaken.

It may be supposed that men who are following industrial pursuits during the day are not in a condition to receive instruction after their day's labor, and that the instruction under such conditions can be of but little profit; but it can be safely stated that such is not the case.

Some persons again have thought that the amount of work attempted in the two years was too large. To be sure, the courses are severe, and there are at present not a large number of men who are capable of following them; but the courses are not planned to reach the greater number of men. They are designed to give training to that group of picked men who are able to profit by the instruction, and who will be able through it to advance to higher positions. For the eight years of the school's history about as many men have been able to keep up with the work as the capacity of the school would admit. It is believed that with the facilities at hand, it is of greater value both to the men themselves and to the industrial community to give this high standard of training to a comparatively small number of men; training that will fit them for positions of foremen and superintendents, rather than to give training of a lesser degree to a larger number of students.

Attendance and Diversity of Occupation.

The average yearly attendance has been about 200 students, 125 in the first-year class and 75 in the second-year class. One hundred and eighty-nine men have graduated, and 30 of this number have attended the school a third year, and are graduates of both the mechanical and the electrical courses. The men have come from about 75 different towns within a radius of 20 miles, and a few from distant cities have taken up work in Boston, in order to attend the school.

A great variety of occupations have been represented, but about half the number of students are draftsmen or machinists. The oldest man to attend was 54 years of age, and the youngest 17 years. The average age of the students at the end of the first year course varied from 28 to 24. The average age of the graduates has varied from 29 to 25 years. A few men have graduated who were older than 40 years, and a number have graduated at the age of 19.

Early Educational Record of Students.

The earlier schooling of the men who have completed the first year course has averaged as follows:

College graduates, 4 per cent.
Attending college, 9 per cent.
High School graduates, 46 per cent.
Attending High School, 25 per cent.
Grammar school graduates, 13 per cent.
Attending grammar school, 3 per cent.

It will be noticed that, although a little more than one half the students have been High School graduates, or better, a considerable number of the men have entered the school with but very little earlier schooling.

Success of the Scheme.

That the school is making men more efficient in their regular occupations, and qualifying them for advancement along the lines in which they are working, has been demonstrated by the graduates. Nearly all of these men have changed their occupations, or have advanced to a higher grade in the same line of work.

There are but few exceptions to the rule that a good workman gets better pay than a poor one. The following facts have been compiled from answers to a circular letter received from about three-fourths of all the graduates:

Average Increase of Salaries.

Two years after graduation, more than 70 per cent.

Class graduated in May, 1910, 72 p.c.

From three to six years after graduation, 107 per cent.

A considerable number of graduates have received increase of salaries greater than 200 per cent., several men have received more than 300 per cent., and one man had an increase of 450 per cent.

A LARGE INGOT.

An ingot weighing 130 tons, probably the largest ever produced in the United Kingdom, has been cast by Cammell, Laird & Co. at their Grimesthorpe Works, Sheffield. It was over 15 ft. long. At one end it measured 9 ft. by 4 ft. 9 in. and at the other, 9 ft. 3 in. by 5 ft. After being slabbed down to about 3 ft. 6 in. thick, which process reduced the weight to around 90 tons, it was then rolled into a mild steel plate. The rolling operation was carried out in the armor-plate mill, which is believed to be the largest and most powerful in the world, and is operated by engines of 12,000 h.p. When the job was completed, the plate measured 18 ft. 6 in. long, 10 ft. 9 in. broad, and 25 in. thick.

R. E. Smythies, who recently arrived in Canada from England has taken a part interest in the Boiler Repair and Grate Bar Co., 69 Adelaide Street, Toronto. The office department will be in his charge, while that of the boiler and grate bar departments will be attended to by A. H. Hett, and J. E. Taylor, respectively.

Not often does the public have the opportunity of hearing some of the great men of the country talk and spin yarns in their leisure moments. A newspaperman was in the Mount Royal Club the other night and happened to be able to get a little group of old railway pioneers together—men who are now financial forces in Canada. One of them, whose name has to be witheld, but who used to be "The Assistant Engineer" out in the Rockies when the C.P.R. was built, tells a tale about himself and a horse—a yellow horse—which is really worth reading. It appears in MacLean's Magazine for August.

Description of the Electric Method of Spot Welding

By Halyard

This Article Gives a Brief Illustrated Description of the Theory and Principle of Electric Spot-Welding, Its Practical Application and Most Suitable Material Thicknesses Treated, Its Strength Compared With Riveted Work, Together With Examples of Tests and Equipment Details. Those Engaged in Sheet Metal Work Will Find the Data Instructive.

THE theory is as simple as its application, and is an adaptation of the well-known principle that a poor conductor of electricity will offer so much resistance to the flow of the current that it will heat, the degree of heat depending on the amount of current and the resistance of the conductor. An incandescent lamp offers a good illustration of this principle. The copper wires leading to the lamp are good conductors and remain cool, but the carbon filament, being a poor conductor, becomes white hot, or reaches a state of incandescence.

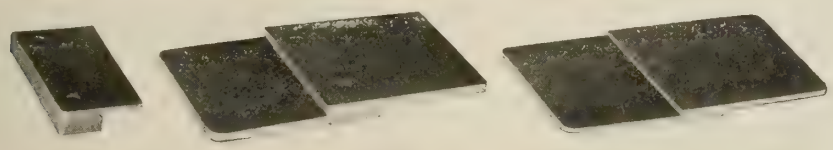

Fig. 1.

Process and Examples.

In spot welding a large volume of current at such low voltage or pressure that it cannot be felt by the bare hand passes through a pair of copper die points; two pieces or more of sheet steel are placed between these points and when the current is turned on with the switch, the pieces of steel offer so much resistance to the flow of current that they instantly become hot at the point opposite the copper dies. The hotter the steel becomes, the greater is the resistance, and automatically the current is forced into the adjacent cooler parts until all the metal in proximity to the dies is brought up to the welding temperature, when a slight pressure on the lever handle mounted on the machine forces the molecules of molten metal together and they are completely and perfectly united. This is done in an incredibly short space of time, taking only a fraction of a second when stock as light as 20-gauge is to be welded. In actual practice one of the copper dies only is pointed and the opposing one is flat. The pointed die leaves a slight indentation on one side of the metal, and the opposite side is perfectly smooth. This is shown by the cut Fig 1, where both sides of a piece of sheet steel and a light piece are welded to a heavier piece.

Examples of Spot Welding.

Fig. 2 shows six pieces of sheet steel of varying thicknesses welded together at one time; also two pieces torn apart near the weld. The metal has been absolutely fused together, and cannot be pulled apart.

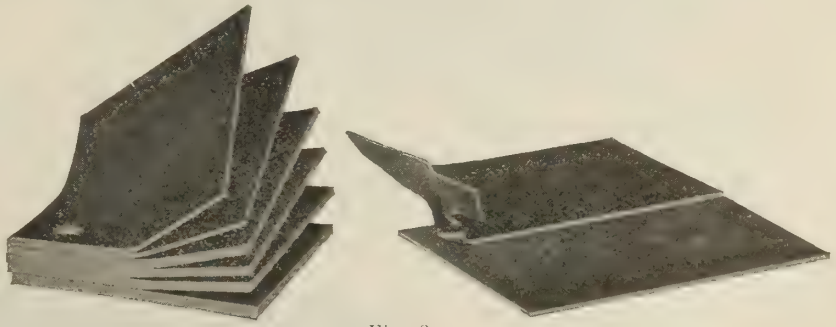

Fig. 2.

Fig. 3 shows front and back view of a spot-welded piece, as also a photographed sectional view of a spot-welded and riveted piece of metal, which illustrates forcibly why the latter will not stand within 60 per cent, as much of a strain as the former. The metal is punched out in the riveted piece, thus weakening it at that point, whereas the spot-welded piece is fused together at the point where the slight depression is seen, making there a complete union of the particles of the steel. A piece of galvanized iron is also shown, and which has been hammered until the metal was torn out in attempting to break the weld apart.

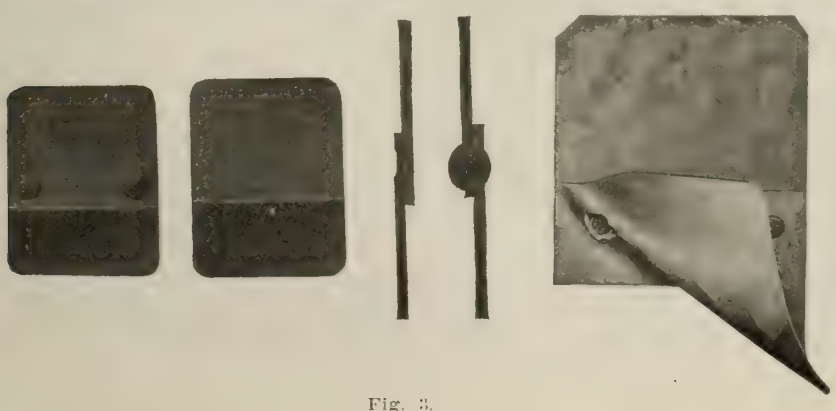

Fig. 3.

Fig. 4 shows a foot-operated spot welder. When the foot lever is pressed down the dies are brought together to clamp the stock, and a slight pressure with the heel on the outside pedal turns on the current to complete the operation. Where it is necessary to have the use of both hands in placing the stock in the machine this type of welder possesses many advantages over the hand-operated machine.

Fig. 5 illustrates a machine especially adapted for stove and sheet metal work. With the extended horn, almost any part of a range can be welded without difficulty.

How to Operate.

Place the stock between the two copper die points.

Pull down on the lever handle to clamp the stock in position.

When ready, touch the switch with the thumb—let go—the job is finished quicker than one can tell about it.

The electric current jumps through the sheet iron and fuses or melts the metal at a point or spot the size of a rivet.

Fig. 6 shows the stove welder described above, with the different parts of the machine plainly marked. The special transformer in the welder is used to reduce the 220 or 440 volts to the

3 to 5 volts used in making the welds. This diagram shows that no auxiliary devices of any kind are required and clearly illustrates the simplicity of the apparatus.

former required in the welder when less than 60 cycles are used, an additional price is charged for welders operating on 25 to 40 cycles. The power factor varies from 70 to 85 per cent., according to the

Fig. 4.

Convincing Test of Electric Welding.

Ten specimens of hoop steel were subjected to a test at the Lunkenheimer laboratory in Cincinnati, with the following result. All pieces were of the same size—1.12 in. by .035 in. Examining this test carefully it will be noted that on

Test No. 1—One spot weld broke at 1,625 lbs.

Test No. 7—One rivet broke at 990 lbs.

Test No. 9—Two spot welds broke at 2,275 lbs.

Test No. 2—Two rivets broke at 1,555 lbs.

Test No. 3—3 spot welds broke outside of the weld at 2,715 lbs.

Test No. 4—3 rivets tore apart at 2,055 lbs.

Current Requirements.

Single-phase alternating current must be used in electric welding. Where two or three-phase current is available, use only one-phase of the multi-phase system. Any voltage from 110 to 500 can be used, but 220 or 440 is preferred, as it is more nearly standard than any other, and all stock machines for quick delivery are arranged for 220 volts. Any frequency from 25-cycle to 140-cycle can be used, but owing to the larger trans-

work, and the way that it is handled. Inside the welder and part of it, is a special transformer to reduce this outside current to the 3 to 5 volts used in making welds. This is so low that it cannot be felt by the bare hand and explains why it is absolutely safe for the operator, as he cannot by any possibility feel the current.

Cost of Current.

Based on current costing 1c per k.w. hour, it will cost from 1c to 3½c per thousand welds. If current costs 3c or 5c, multiply the price given below by the rate charged by the lighting company, to give the actual cost per thousand welds.

Welding Data.

Gauges of Sheet Steel	Thickness in Fract. of inch.	Thickness in Dec. parts of inch.	Approx. K.W. Cap.	H.P. at Dynamo.	Time in sec. to weld.	Cost per 1,000 weld at 1c K.W. cts.
10	9-64	.140625	18	25	1.5	3½
12	7-64	.109375	16	23	1.3	3
14	5-64	.078125	14	20	1	2¾
16	1-16	.0625	12	18	.9	2½
18	1-20	.05	10	15	.8	2¼
20	3-80	.0375	9	14	.7	2
22	1-32	.03125	8	13	.6	1¾
24	1-40	.025	7	11	.5	1½
26	3-160	.01875	6	9	.4	1¼
28	1-64	.015625	5	8	.3	1

No preparation of stock is required unless it is very rusty or scaley; in which case it will be found economical to clean off the rust or scale, as more current is used than on clean stock. Based on using fairly clean stock, the above table will give an idea as to the time and current required in welding different gauges of sheet steel.

Welding Limitation.

There is a limit to the thickness of sheet metal that it is practical to spot weld. This is due to two causes, 1st, the fact that the copper rods which conduct the electric current can only carry a certain quantity of current without excessive heating. When sufficient current is carried over these copper rods or

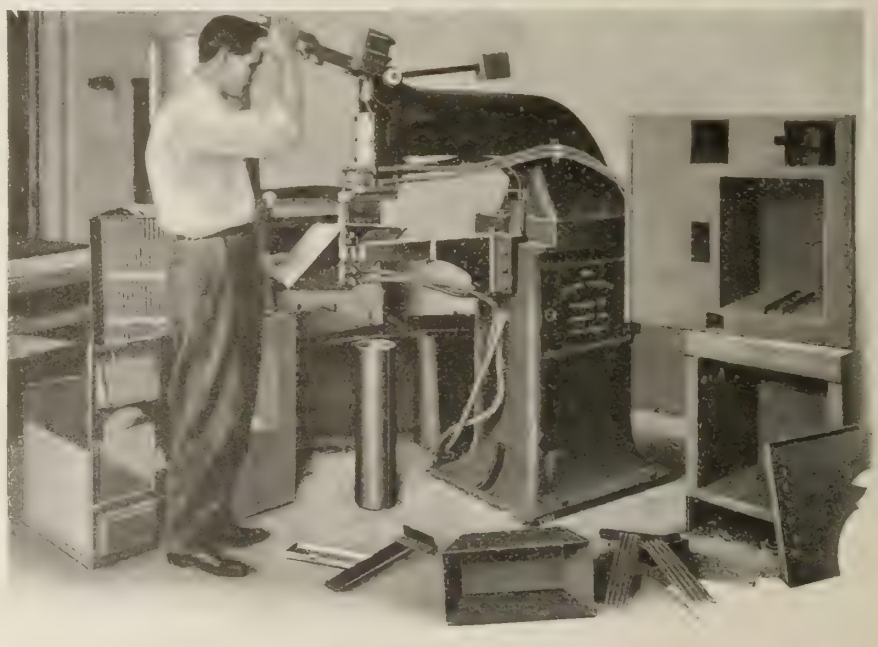

Fig. 5.

die points to bring very heavy metal between them up to the welding temperature, the copper rods will become so hot they will soften and the points wear away so rapidly that it is not practical to use them for this kind of work. 2nd, It is necessary to have the two pieces of metal touch each other at the point where the weld is made. With very heavy stock, a slight kink or buckling of the metal will prevent the flat surfaces from making good contact. Stock as heavy as 3-16-in. or ¼-in. can be welded, but the best results are obtained when ⅛-in to ⅛-in. or lighter are welded.

Copper and brass cannot be spot welded for the reason that they are both good conductors of electricity and offer no resistance to the flow of the current. It is impracticable to weld cast iron, as there is no fibre to stock of this kind and the metal will tear out at the welded spots. Galvanized iron can be welded, although it will burn off the zinc, leaving the iron exposed at the point where the copper dies come in contact with the metal. Heat has no effect on the electric weld, and for this reason this process is largely used by stove manufacturers in making sheet steel ranges and similar work. It is not practical to make more than one spot weld at a time, as it is almost impossible to make a number of die points bear on the stock with equal pressure, and the one die point making the best contact will carry all of the current, and the result will be that with so much current concentrated at this point the metal is liable to be burned. The machines used for this work can be furnished either hand-operated, foot-operated or power-driven. A depth of throat can be furnished from 6 to 48 inches, and a variety of types are made to suit almost any kind of sheet metal work where rivets are used. The "Toledo" Electric Welder Co., of Cincinnati, Ohio, are the manufacturers of these machines and their catalogue shows a number of different types adapted to this class of work.

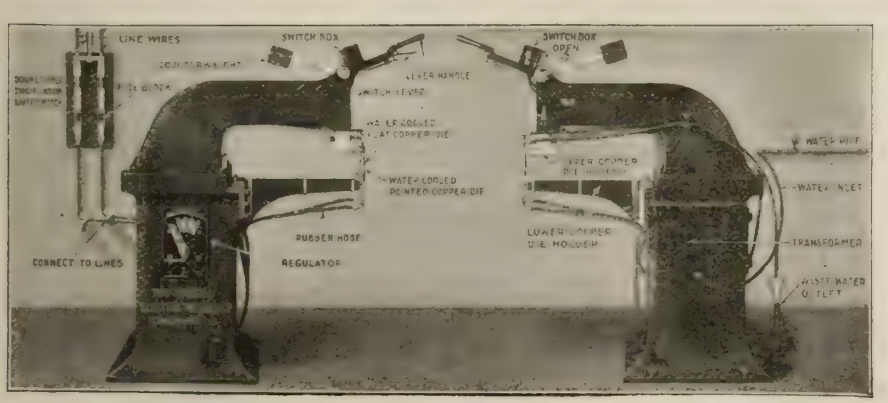

Fig. 6.

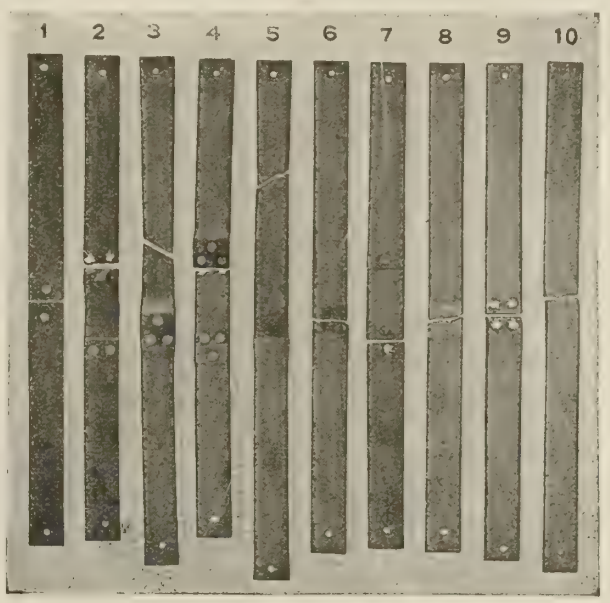
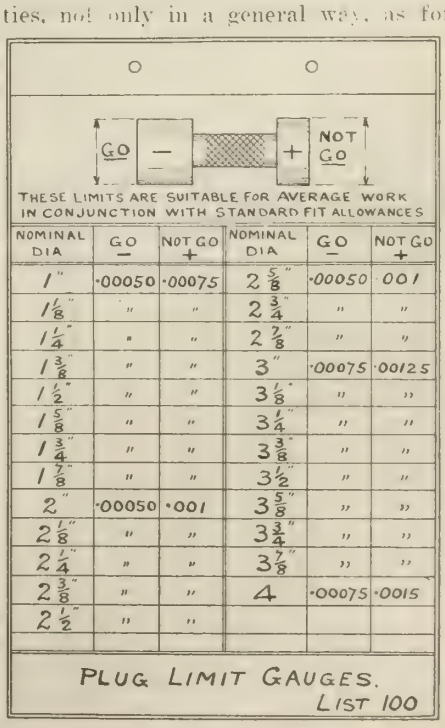
Standardizing Equipments and Fits

By Harold Smith, Toronto



This Article is the Second of the Series; the First having Appeared in our July Issue. The Writer is an Expert on Standardization Work, and Consequently Speaks with Confidence, Born of Experience. Machinery Manufacturers, on a Large or Small Scale, will find the different Subjects Treated, Both Interesting and Profitable.

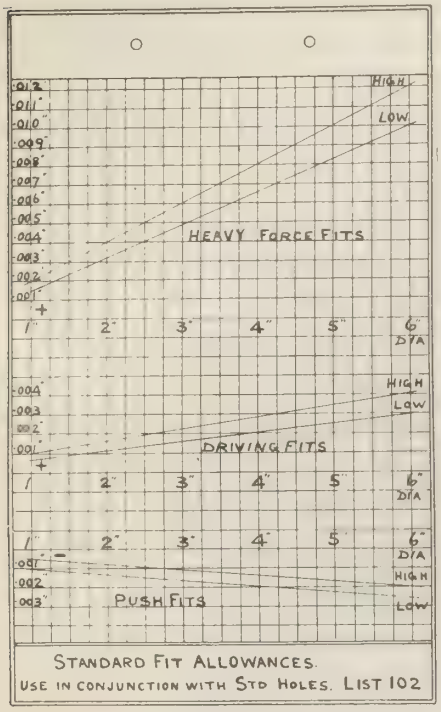
IN a recent paper on the manufacture of large gas engines, it was said that:—"To design without reference to the machine tools available is an easy matter, assuming the necessary tools to be specially constructed for your purpose. Such a design although possible, and at the same time good, would mean more costly manufacture, because of increased capital outlay for such tools, unless a very large output could at once be obtained to enable them to be fully worked.



A really successful design is one that employs a range of standard machine tools in a particular workshop for the whole of their time at economical speeds of working, and produces a high-class engine with the largest output and lowest capital cost."

Shop Practice and Design.

This is true of all machine shop work, and necessitates designers becoming more and more intimate with all details of their firm's shop practice and possibilities, not only in a general way, as for



Electric Welding Test Specimens.

USE IN CONJUNCTION WITH STD HOLES. LIST 102

this matter, and to a certain extent predetermine what equipment it is advisable to carry in tool stores, to handle their particular business in the most economical way, and so that the right minor tools will always be ready for use. This is of course a simple matter, where only special lines or styles of machinery are manufactured, and where equipment is specially designed for the purpose. Where a general business is carried on, the matter is more complex, but this is now being solved to a considerable extent by standardization of parts, machine operations and equipment, as also by the embodiment of certain definite principles in design.

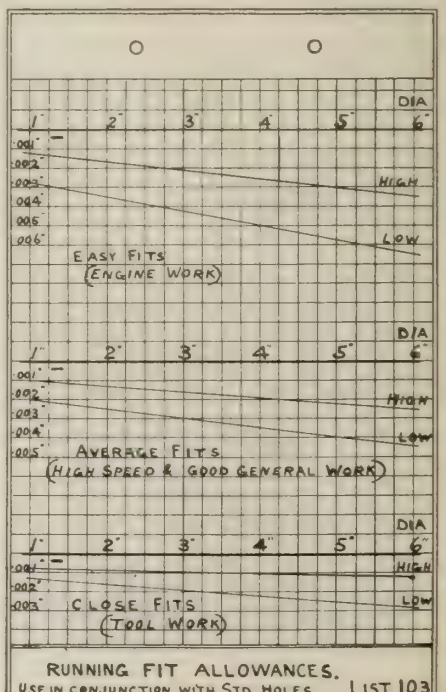
Standard Holes.

It should be insisted that holes are kept standard size and outside diameters made large or small to suit the class of fit. There is no difficulty in doing this where both hole and outside diameter are to be machined, and in cases where it would seem more economical to reverse this rule (as for instance where cold rolled steel shafting is used), it can be overcome by designing with some small amount of machining. Moreover, most manufacturers of cold rolled steel make their product a few thousandths small (about .001 inch for each 1 inch diameter) for push and running fits, and any press fits required, can be obtained by slightly reducing the diameter in the lathe or grinder to the next nominal dimension, e.g. from 1 15-16 inch to 1⅞ inch plus the press fit).

The importance of standard holes cannot be too strongly emphasized, as it enables the shop for quite a reasonable outlay to have reamers, boring cutters and boring bars standardized for different sizes of hole and always ready for use, no matter what shape of article is to be tooled, so long as it is a boring job. By keeping holes standard, reamers can be used on almst all work, which means that accurate boring can be produced at a commercial cost which is not attainable with a bar and point tool. It may be claimed that with adjustable reamers, the diameter can be made large or small to suit, but this adjustment is a continual expense, and the tool when required by the lathe hand will never be ready for use, causing him delay and eating up any possible saving. The object of the adjustable feature is to take up wear, and not to cover a range of diameters.

Again, with standard holes, gauging and testing can be accurately done by plug limit gauges, to a degree impossible with the single standard plug gauge, which, if a hole is to be made small, we cannot tell just how small, as the gauge will not enter. If standard, and lathe hand allows it to just enter, we know it must be a little oversize at the mouth, and probably tapers further up. If oversize, the gauge goes in, the amount of excess is estimated by the feel, and therefore not in any positive manner.

The limit plug gauge, on the other hand, tells at once that the hole is commercially accurate within certain necessary limits and without any personal errors from judgment or touch. There will be one definite gauge for each definite hole. Standardization of holes therefore means that for quite a reasonable outlay, the shop is prepared to handle either small or large lots of boring and chucking work in an accurate and economical manner, and that even turret lathe equipment which smacks of specialty, is always ready for use and possesses a degree of flexibility comparable with the simpler but less productive engine lathe.



Machine Tool Standardization.

Standardization can be introduced into the machine tools themselves. The spindle noses of lathes can be re-threaded to be same pitch for same diameter, so that chucks will fit any lathe. Where this change is not possible, adapter plates can be made. The taper holes in milling machine spindles as produced by different makers are not always the same standard; more particularly is this true of older machines which were made Morse, as against present Brown & Sharpe. They should be re-reamed to fit standard arbors. All this means a smaller outlay in minor equipment, to supply quite a number of tools which may be employed on a variety of work coming through in small quantities.

The variety of sections of tool steel for lathe and planer tools can often be reduced by modifying the tool posts somewhat, so as to take predetermined standards, thus reducing the stock of idle tools and tool steel, which is no small item when of high speed quality. The common practice of stocking lathe, planer and shaper tools of standard types, all ground to correct angles is a step in the same direction.

It should be appreciated that accuracy and a definite commercial cost are the objects aimed at, and that there are exceptions to all rules. Clearance holes must not be confounded with fits. A gland for instance has a clearance hole, and as commercial accuracy say for a 2 inch. nominal diameter is satisfactory if within .0025 over and .0015 under; giving a margin of .004 inches. A coupling forced on to the same shaft for a press fit would have to be not more than .001 inches over, and not less than .0005 inches under, giving a margin of only .0015 inches. Commercial accuracy is a varying quantity.

Where rougher work is allowable, it is quite possible that it may be in some cases cheaper to break away from these standards, but as the modern tendency in machinery design is to reduce clearances and increase speeds, this demand for accuracy (which competition demands shall be produced at low costs) is growing stronger every year, and the manufacturer who is turning out but one

RUNNING FIT ALLOWANCES.
USE IN CONJUNCTION WITH STD HOLES. LIST 103

class of goods will be compelled to keep his costs down by adopting some method of standardization.

The foregoing is a mere outline of methods successfully adopted. Each shop has its own peculiar problems, and is best in a position to solve them, and though the details will differ in every case, yet the principle judiciously applied, holds good for all.

Fit Allowances and Standard Hole System.

The accompanying cuts show details of average fit allowances, based on a system of standard holes. It will be noted that the impossibility of absolute accuracy is appreciated throughout; limits between which it is commercially possible to produce work accurate enough for a particular class of machinery, being specified. Thus, (list 100) for a 3-inch fitted hole, the work is considered a good job, if not more than .00125 inch. larger than standard, or more than .00075 smaller, giving a total working margin of .0005 inches. The— GO. end of the gauge is allowed to enter, and the + NOT GO, not allowed. As the — GO. end thus necessarily gets the wear produced from usage, it is made the longer, and this difference of length also serves as a ready means of distinguishing the two ends, when gauging.

Lists 102 and 103 show allowances and limits on external diameters for different fits. When allowance is above the line +, the finished diameter is larger than standard, requiring force to drive it home into a hole. When below the line —, the finished diameter is less than standard, making a push or running fit. Here again, limits "high and low" are specified, between which work is commercially accurate for different classes of machinery. Thus, a 4 inch running fit for engine work, should be between .0024 and .005 inch small, giving a working margin of .0025 inch. The same fit for tool work should be between .001 and .002 inch, giving a working margin of only .001 inch. Locomotive work again, would require a different scale.

Recent Drilling Records

AT the recent joint conventions of the Railway Master Mechanics and Master Car Builders Associations held at Atlantic City, June 14th-21st, 1911, much interest was aroused by some phenomenal results obtained in a demonstration test of twist drills. As the durability and efficiency of tools are such important factors in economical production, these results should be welcomed by all interested in this subject.

Test Results.

The Cleveland Twist Drill Co., of Cleveland, had a Foote-Burt No. 25½ high duty drill press in operation in connection with their exhibit, and the results obtained from tests of Cleveland milled and flatwist drills taken from stock, are tabulated below:—

Size and Kind of Drill	Material	R.P.M.	Feed per Rev.	Inches Drilled per Min.	Peripheral Speed in ft. per Min.	Cu.In. Metal removed per Min
1¼ Paragon	CAST IRON 3½ inches thick	500	.050	25	163.6	30.68
1¼ "		325	.100	32½	106	39.88

*This is the highest drilling speed on record.

Official Record of the Tests.

The first tests made were for the purpose of demonstrating what is good shop practice, i.e., the drills were put through at speeds and feeds that would be economical under average shop conditions. Then, to demonstrate the reserve efficiency and durability of the drills, "stunts" which demanded extremely high rates of speed and feed, were attempted. The highest rate of speed in drilling known to machine shop practice was attained by a stock 1¼ inch Paragon flat twist high speed drill in successfully removing 70.55 cu. in. of cast iron in one minute, repeatedly cutting through a heavy billet at the record-breaking rate of 57½ inches per minute or nearly an inch per second. This drill ran at 575 r.p.m. with 1-10 (.100) in. feed per revolution, successfully withstanding the great strain of this extreme speed, and feed. Before attaining this maximum performance, which was approached gradually, numerous other "Cleveland" Drills were put through at the rates of 25, 32½, 33½, 35 and 47½ inches per minute. In no case was the limit of strength of the drills reached, although the speed of 57½ inches per minute could not be exceeded, on account of the inadequate capacity of the electric feed wires, which brought current to the motor driving the drill press.

Drilling at such high speeds and heavy feeds is not to be recommended as economical shop practice, and this performance will in all probability not be repeated in many shops. These results were only made possible by carefully established ideal conditions, such as:—absolute rigidity in the machine, uniform and sufficient driving power, solid clamping of the work, perfect grinding of the tool and most expert handling. They are of value chiefly, as demonstrating the power and rigidity of the machine, and the exceptional reserve strength of the drills.

Another noteworthy test was made with a 2½ inch. milled drill from stock. It drilled 68 holes through a billet of machinery steel 4¼ inch. thick, without being reground, and was operated at 150 r.p.m., with a feed of .015 per revolution, removing a total of 1418 cu. in. of material. Although the drill was still in good condition, the test was cut short at this point by the convention coming to a close, yet there was demonstrated what can be done all day long in any shop properly equipped, and indication given of what results may be expected in economical high speed drilling.

Bulletin of drilling test.

The Apprentice Question

SPEAKING at the eighth annual convention of the Master House Painters' and Decorators' Association of Canada, held recently in Toronto, W. E. Wall, Somerville, Mass., said that now-a-days the average master mechanic is unwilling to reach his trade; a contingency largely due to his time being fully occupied in other directions. The tendency, therefore, is for the apprentice to be left in the hands of underlings, whose knowledge at the best is somewhat superficial. The day is long since past when master and men worked hand in hand. Numbers of young men who desire to learn a trade are thus unable, and drift into the already overcrowded unskilled labor market.

Comparatively few of those who pass through the High School, go on to college, yet all receive a training which is of a preparatory nature, and which does not benefit them in the least. As a result, large numbers of High School graduates may be found to-day, holding down jobs which could be filled equally well by men who had received only an elementary training.

To show the difficulties which confront the would-be apprentice, Mr. Wall cited an instance which had come to his notice, of a lad who, wishing to learn harness-making, had tried vainly for a long time to become apprenticed, and finally committed a slight crime so that he could be sent to a reformatory where the trade was taught.

Trade Schools the Remedy.

Having pointed out the difficulties which beset a young man, the speaker entered a most emphatic plea for the trade school. He suggested that manual training should begin in the primary school, so that by the time the child reached an impressionable age, he should have had an opportunity to show adaptability for some particular art or trade, in which he might receive further instruction at the High School, and later in a Special Trade School. It is a well-known fact, said Mr. Wall, that America which is one of the greatest mechanical producers, cannot produce mechanics, and that the majority of the foremen in mechanical factories in the States are men who have been trained in England or Germany.

Benefits Assured.

In conclusion, Mr. Wall said that one year in a Trade School would be of more benefit to a lad than two under the apprenticeship system, for there would be nothing to detract the learner's attention from his work, while the instructor would be unhampered by the commercial considerations which must needs affect the master mechanic, and so would be able to give his undivided attention to the training of his students.

Spur Gears

By G. D. Mills, Montreal.

IN the design and layout of spur gears, it often becomes necessary to calculate the strength of the teeth. As the Lewis formulae takes account of so many variable conditions, they may be safely used for that purpose, and are as follows:

Mr. Lewis gives three formulae for determining the value of "y"; see Kent's pocketbook, page 902. The values in the table on the preceding page, are however, evidently obtained from a plotted curve.

Lewis' and Flanders' Formulae.

In the proceedings of the American Society of Mechanical Engineers Vol. 30, 1908, a very able review of the subject is given by Mr. Flanders, in which he compares the values obtained originally by Mr. Lewis, with his own in a plotted diagram. The increase he obtains being accounted for, by reason of the fact, that he has lengthened the rack tooth a distance equivalent to the clearance, and strengthened the corners by a fillet, whose radius is equal to 2-3 of the clearance. This may be considered an improvement, in keeping with the demand for a strengthened tooth. Mr. Flanders' values are obtained from the original formula $W = \frac{s.f.y.}{P}$, in which "P" is the diametral pitch, "y" equal to 3.1416×"y" in the Lewis formula, and "f." "s." the same as the Lewis values. The tooth parts also correspond to those given in this article.

In order to embody here the results obtained by Mr. Flanders, which, by the way, are endorsed by Mr. Lewis as an improvement, I have divided Mr. Flanders' values by 3.1416, to make them correspond to the Lewis formula, and have obtained the two equations by which "y" is determined for 20 degrees and 14½ degrees obliquity. The table of constants "y," and also the equations, therefore, differ slightly from those originally published. Respecting the safe working speed stress, the values in the table are evidently obtained from plotted

LEWIS FORMULA.

$W = s\ p\ f\ y$

W = safe load in lbs

s = safe working stress of material in lbs "see table of stresses"

p = circular pitch

f = face length of teeth

y = constant from table of constants "y"

$y = .149 - \frac{.776}{n}$ for 20° obliquity involute

$y = .139 - \frac{.737}{n}$ " 14½° " & cycloidal

n = number of teeth

$Horsepower = \frac{W\ v}{33{,}000} = \frac{s\ p\ f\ y\ v}{33{,}000}$

v = velocity in feet per minute

$v = \frac{D \times 3.1416 \times rpm}{12} = D \times .2618 \times rpm$

D = pitch diameter in inches

rpm = revolutions per minute

"LEWIS" Constants "y"

number of teeth	20° Involute	14½° Involute & Cycloidal
12	.084	.077
13	.089	.082
14	.093	.086
15	.097	.090
16	.101	.093
17	.104	.096
18	.106	.098

21	.112	.104
23	.116	.107
25	.118	.110
27	.121	.112
30	.123	.115
34	.126	.117
38	.129	.120
43	.131	.122
50	.134	.124
60	.136	.127
75	.139	.130
100	.141	.132
150	.144	.134
300	.146	.136
Rack	.149	.139

curves, derived from the formula, $S = \frac{600}{600 + \text{velocity in feet per minute}}$. It will be noticed that the quantities .139 and .149, are the rack values for "y" in the table, and the value of "y" for any number of teeth not tabulated may be readily determined.

Spur Wheel Design

Spur gears form the greater part of all machine gear drives, and are usually arranged in pairs, and in groups, to transmit the required speeds and horsepower. The calculations which are necessarily a part of the design of a box or group of gears are usually extended, and often include the diameter of cone steps, controlling mechanism, etc. While it is not the intention to introduce in this article the principles of group design, we shall, however, consider the design of a pair of wheels, which are required to transmit 3 horse power, and have a speed ratio of 3 to 1. The driving shaft makes 40 revolutions per minute, the gear or larger wheel is to be the driver, and the distance between centres is, say, 6 inches. By referring to the Lewis formula, we find the horsepower $= \frac{W.V}{33{,}000}$.

$W = \frac{(D \times .2618 \times \text{r.p.m.}}{33{,}000}$, therefore $3 = \frac{W(D \times .2618 \times \text{r.p.m.}}{33{,}000}$. Determining the velocity, we have the revolutions per minute, the pitch diameter, which can be calculated from the distance between centres, and the speed ratio.

Pitch diameter of Gear $= \frac{C}{R+r} \times r \times 2 = \frac{6}{1+3} \times 3 \times 2 = 9$ inches, therefore, $3 = \frac{W.(9 \times .2618 \times 40.)}{33{,}000} = \frac{W \times 94.248}{33{,}000}$, from which equation we may write the proportion, 3:W: : 94.248 : 33,000. The value of three terms being known, the remaining term "W" $= \frac{3 \times 33{,}000.}{94.248} = 1050$ lbs.; in other words, the load which the wheels will labor under, to transmit 3 horse power. If we decide to make the wheels of cast-iron, we have one of the components of this load, the value of "s" for a velocity of 100 feet per minute or less. As W=s.p.f.y.=8000×p×f×y, the value of p, f, and y. can be determined from a selected diametral pitch.

In the table of tooth parts will be found a column of circular pitches for each diametral pitch, and also a column of face lengths, the latter being calculated in even lengths of about 2½ times the circular pitch. Selecting in this case, 5 diametral pitch, "p"=.6283 and f= 1 9-16 inches. The number of teeth by which to determine the value of "y," can be found from table of tooth formulae. N=D×P=9×5=45 teeth, and the value of "y," .123, obtained from table of constants "y." We, therefore, have W=8000.×.6283×1 9-16×.123=966 lbs.

If 5 diametral pitch is selected, the gear will have insufficient strength to develop 3 horse power on a load of 1050 lbs., but the necessary load can be obtained by increasing the face length of T diametral pitch, or by selecting the next diametral pitch, which is 4. The number of teeth of 4 diametral is 4×9=36, and the value of "y" from the table becomes .118, therefore W=8000×.7854×2.×.118=1482 lbs., which is well over the required load, and the teeth, therefore, amply strong.

"LEWIS"

SAFE WORKING STRESS FOR DIFFERENT SPEEDS.

Speed of Teeth in feet or minute	100 or less	200	300	600	900	1200	1800	2400
Cast Iron	8,000	6,000	4,800	4,000	3,000	2,400	2,000	1,700
Steel	20,000	15,000	12,000	10,000	7,500	6,000	5,000	4,300

We shall select 4 diametral pitch then, and determine the size and strength of the pinion. The number of teeth in pinion, obtained from the speed ratio of 3 to 1 is $\frac{36}{3}$=12, and the value of "y" from table is .077. For a cast-iron pinion the load W=8000×.7854×2×.077=967 lbs. As the strength of a pair of wheels is measured by the strength of the weaker of the two, it is evident that if the pinion is made of cast-iron, the pair will not have sufficient strength to carry the load. Also, as the pinion is subjected to three times the wear imposed on the gear, it is advisable to make the pinion of steel. The value of "s" for steel at a velocity of 100 feet per minute or less is 20,000, and our load W=20,000×.7854×2×.077 = 2419 lbs., which is amply sufficient. The tooth parts may be obtained from 4 diametral pitch, in table of tooth parts, and noted on the drawing of the wheels, Fig. 2.

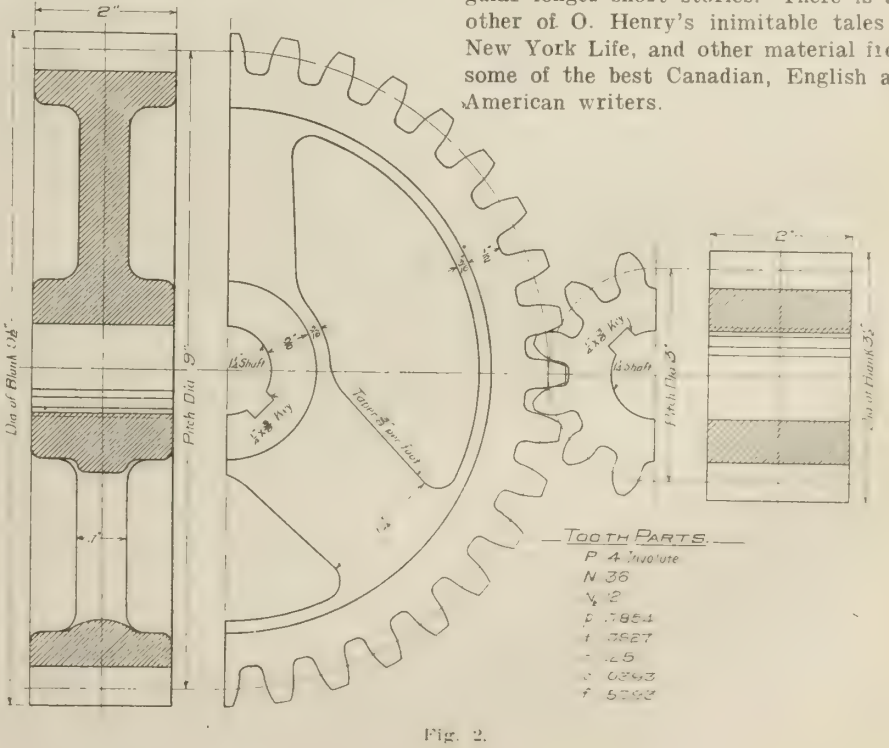

Fig. 2.

For six months the editorial department of MacLean's Magazine has been collecting little short stories from Canadian writers, until now there is a large enough stock to allow the magazine to give in the August number several of these "Little Tales for Summer Weather" all at once. There is "The Green Hour," by Deshler Welsh, a regular contributor for the better American Magazines. Then "Sally's Soul", "The Lonesomeness"; "Music Hath Charms"; and others, offer short, crisp reading for these hot months. Of course, in addition to these articles there are the regular longer short stories. There is another of O. Henry's inimitable tales of New York Life, and other material from some of the best Canadian, English and American writers.

Conference on the Education and Training of Engineers*

By G.T.R.

The Object of This Conference Was to Consider the Methods of Preparation to be Adopted by Those Who Contemplate Entering the Engineering Profession. While the immediate Purpose Was That of Compliance With the Conditions Laid Down in the By-laws for Election to the Institution of Civil Engineers (British) the Scope of the Field Involved Makes the Work Done at This Conference of the Greatest Interest and Moment to All Engaged in Mechanical Pursuits.

A CONFERENCE on the "Education and Training of Engineers," was held at the Institution of Civil Engineers, London, Eng., on June 28 and 29, Mr. Alexander Siemens president of the Institution, presiding. The work of the conference was divided into three sections, as follows: First—General Education. Second—Scientific Training. Third—Practical Training. Each section had individual chairmen, in the persons of Anthony G. Lyster, Professor W. C. Unwin, and R. Elliott-Cooper, respectively. The sectional arrangement was based on the Institution by-laws, which require that a candidate for membership should possess. First—A sound general education developed on lines suited to subsequent scientific study; Second—A competent knowledge of those branches of science which formed the basis of engineering; Third—Practical training under actual engineering conditions

President's Opening Address.

The president, Mr. Alexander Siemens, in his opening address said that the problem submitted to the conference might be expressed by saying, that a young engineer should be educated so as to become a dividend-earner for his employer, for this was the most reliable indication of his merit, and the corresponding reward would not be wanting. For the same reason, he should possess some knowledge of business methods and of law, not with a view of becoming his own lawyer, but in order to be able to judge when legal advice was needed. Besides all these requirements he would find one or more modern languages very useful for obtaining remunerative employment, as the value of his services was thereby increased in the estimation of his employer. The omission of this "business" aspect of education should not be taken as a sign of its unimportance, but owing to the short time at its disposal, the council considered it desirable to indicate the lines to be followed, by asking a number of prominent men to open the discussion on definite subjects in the three sections of the conference, all of which had a direct bearing on the question of so instructing young men as to fit them to take part in the design, as well as in the control and direction of engineering works.

It was not proposed that definite resolutions should be arrived at by the conference, but that it should be simply a means of forming and maturing the views of those interested in the subjects brought forward for discussion.

Sir William White.

Sir William White, late chief constructor at the British Admiralty, said they were apt to forget that the average student was the man they should provide for, and that the exceptional man, whether he became, like the first Lord Armstrong, an engineer by necessity, or found his way up from the humblest position to the highest ranks by sheer ability, would always take care of himself.

He stood amongst those who thought that the danger of excessive devotion to the scientific side was very considerable in these days, and that the Institution was doing well in recalling attention to the absolute necessity for a thorough practical training. For a long period British engineering was not based on scientific methods to the extent it ought to have been. Then when the scientific training began, there was the danger of undue exaltation of such knowledge. He took it that in that conference, an endeavor was to be made to reach the golden mean.

Sir John Wolfe Barry.

Sir John Wolfe Barry said he entirely agreed that the best practical training should be given the engineers, and having been president when the examination system was set on foot, he thought perhaps he ought to say that the particular work which had to be taken in hand at that time, was the scientific preparation of engineers for their profession, and which up till then, had been neglected so far as the conditions of belonging to the Institution were concerned.

The necessity for a grounding in the scientific lines of the profession was felt to be important, and he thought they had done rightly in giving a prominent place to it when the system of examinations was started, although he believed the council always foresaw that to be only part of the business. At that particular time it was the essential part, and no one could doubt that the status of engineers in the scientific world and the world at large had been very considerably raised by the step which was then taken. The practical part of the training of an engineer had, of course, always been to a certain extent provided for by the by-laws of the Institution, and what was being done now was rather to give form and substance to the general regulations concerning practical training. To that extent he was entirely in accord with the general views which had been put forward by Sir William White.

There was another point on which he had felt strongly for some years, which was, that the general education of an accomplished gentleman should not be lost sight of in the curriculum of the engineer. What they all wanted, was to turn out an engineer as a cultured gentleman, with scientific knowledge of his profession, and with that practical training, without which he could put neither the one nor the other into use in the career which might lie before him.

Sections I and II—General Education and Scientific Training.

The sections devoted to general education and scientific training met jointly under the chairmanship of Mr. A. G. Lyster, who in the course of his opening remarks emphasized the importance of the conference. The general education of young men desiring to become engineers required the closest attention of those who, on the one hand, realized what the necessities of the profession demanded, and those on the other hand who controlled the selection and organization of education; and so it seemed very fitting that, in contradistinction to the too prevalent practice of "muddling through," the heads of the universities and public schools should meet the members of the profession, and discuss with them the best preliminary training for those who were hereafter to uphold its traditions. Education to be of real value should not only furnish information and knowledge, but should also train and expand the intelligence and develop that type of character which fitted

*First of a series of articles.

a man to lead the best and most useful life; and all subjects and methods which could produce this result should be included in the curriculum of universities and schools.

It should be remembered, however, that a great many of these institutions were founded and organized in days when the conditions of life were very different from what they were to-day, and certainly much less strenuous, and when competition, both individual and international, was much less keen. The choice of professions, too, in those days was much more limited, and so the curriculum established was one which lent itself much more to the development of scholarly culture than to the practical requirements of those who to-day had to fight the keen battle of life. With an ever-increasing intensity of struggle, and with the development of science ever enlarging its boundaries, and multiplying its complexities, the demand for special training for the engineer became increasingly urgent, and unless he was to be debarred from the universities or public schools, it behooved the authorities to bring their educational standards into line with modern requirements.

Engineering Degrees—Note I.

The section devoted to scientific training began its separate work with a discussion of the value of a university degree in engineering science, in relation to professional competence.

In the first note, Professor S. M. Dixon said there was no doubt that the work carried out for the degree must deal mainly with principles, and should be as broad as possible. Details of current practice would be noticed only as illustrations of principles. In dealing with materials, the engineer needed a knowledge of mathematics, physics and chemistry, and if he was to avoid mistakes, his knowledge must be very exact and at his finger ends. The courses in mathematics, physics and chemistry naturally led to those in surveying, stresses in structures, and properties of materials. All these were technical subjects, but they could be far better and more easily taught in the class-room, field, laboratory, and drawing office of a university than in the engineer's office. A liberal education also was essential. Literature, history, philosophy, and all subjects which tended to broaden a man's outlook, should be studied, this being even more necessary in the case of engineering students than in the case of those who intended to follow other professions.

The general culture which came from college life as well as from college study was an asset in the engineering profession, not to be despised and not easily obtained. The man who led his fellow-students in the class-room, in sports, or in the debating society, was equipped in a very real way for success in his profession. The final examination was but a very small part of the requirements for a degree. Three or four years of solid work under personal teaching, sifted out a large proportion of those entering on the courses, while at the same time few students who possessed industry and average ability should fail to satisfy the present requirements in the specified time.

At present the university method was recognized as the only generally applicable method in every country but our own. The objections to the system in this country were stated by two classes of engineers; those who had in their early days entered university courses and then dropped them before grasping the meaning of the instruction offered, and those who had risen to eminence in their profession before university training in this country became general. The former were answered by the fable of Aesop, in the fox who tried to make the best of a serious accident; the latter were reminded that competition in the profession was becoming keener every day. English engineers now found in every country friendly rivals who had spent a large part of their time at engineering colleges, and it would be unjust to the rising generation if they were not able to start with advantages equal to those of their competitors.

While in other professions a university degree was regarded as the first requisite, and so led directly to employment, there was still a feeling in some quarters that the university graduate was rather in the way in an engineer's office. Matters, however, were improving. Once engineering firms recognized the advantage of having assistants thoroughly trained in the principles underlying practice, whose training also specially fitted them for adopting new ideas rapidly, they would be only too glad to co-operate with the universities in completing the education of the engineer.

Engineering Degrees—Note II.

In a second note on the same subject, Professor C. F. Jenkin said that in order to estimate the value of a degree in engineering science, it was necessary to understand clearly what the possession of the degree meant. It meant that the graduate had spent some years in passing through a carefully arranged course of study in those fundamental subjects which should form the basis of engineering education, and also that he had attained a certain standard of proficiency in them, as far as that could be tested by examinations. A degree was a very much better proof of the possession of a good theoretical training than any examination could be. That an examination was in general a poor expedient for ascertaining a student's proficiency was becoming more widely recognized every day; it was, however, less unsatisfactory when held on the completion of a definite course of study, than when it was used as a test for general scientific knowledge. Further, the degree course contained much that could not be included in the examination at all. For example, much of the student's time was spent in the laboratory, learning how to measure accurately all sorts of physical quantities, and to carry out tests on all sorts of machines. Again, there was the teaching in the drawing office, where the student learnt to use his theory in the preparation of actual designs, and the the field course of surveying, during which he learnt to handle his instruments skilfully and accurately. These were all implied in the degree, but it was almost impossible to take any account of them in an examination. Again, to spend some years at a university was an education in itself, and would be a permanent asset in the boy's life, while if the engineering profession was to be brought under State control, as medicine was, and also the law— in a modified sense—it would appear to be wise, to make the basis of qualification as broad as possible, by recognizing the engineering degrees of the universities as a necessary qualification, rather than a certificate by a single institution, even although that institution were their own.

Section III.—Practical Training.

The chairman, Mr. Elliott-Cooper, in his opening remarks, suggested the necessity of agreement as to what was meant by "practical training," and said that the first point he wished to make clear, was that real and useful practical training, whether in design, construction or management of works, could be obtained only under the actual or commercial conditions which necessarily could not be found in educational establishments. The routine (under proper supervision) of the drawing office and works, whether in the civil or mechanical branch, was just as important now as it was considered in former days, the only difference being, that the young engineer of to-day was better equipped, by reason of the advance in scientific education, to take advantage of the practical training afforded him. To deal for a moment with "civil" engineering (as distinct from mechanical engineering), it was obvious that any efficient training must embrace experience in various

kinds of work, such as designing, drawing, specifying and estimating, all of which would be part of the ordinary routine of an engineer's office. He must also be trained in construction work, embracing, setting-out, measuring up, and general administration. Many young engineers made the great mistake of thinking that all that was necessary on completion of their college career to make them efficient assistant engineers, was either to go into a workshop and spend, say two years on the ordinary work of a mechanic, or (if "civil" engineering was to be the career) to go to a contractor upon some works of construction. The knowledge so gained was most useful, but without the office training they were only half equipped for the work of their profession.

Apprenticeship and Pupilage.

There was doubtless a belief in some quarters that the system of training by definite apprenticeship and pupilage, which was certainly affected and modified some years ago, by reason of the movement in favor of better scientific education, had fallen largely into disuse, and statements were sometimes made that it had been actually abandoned by the majority of engineers. Such an idea could arise only from an imperfect or very partial acquaintance with the engineering profession. An inquiry made on behalf of the council some months ago, in order to ascertain the position of pupilage, or other equivalent practical training, in manufacturing work shops and in the engineering departments of important railways, docks, and other large undertakings and authorities, showed that in 75 per cent. of the cases considered there were regular arrangements for pupilage, and in only 25 per cent. was no provision made for such regular practical training. Of the 25 per cent. more than half the cases occurred in the engineering departments of municipal authorities, which certainly might be expected to make better provision for the acquisition of practical training of a kind suited to prepare young men to become competent municipal engineers. The inquiry was not addressed to engineers in private practice, but it was a matter of common knowledge that the system of pupilage remained extensively recognized amongst consulting engineers, although the requisite term of such training had been shortened, in view of the better educational qualifications now generally possessed by young engineers.

Works Training and Scientific Study.

A note on the "Apportionment of Training between Practical Work and Scientific Study, with some suggestions Applying to Apprentices in or on Works far distant from their Homes," was contributed by Mr. A. F. Yarrow and members of his staff.

Dealing with the social aspect of the "sandwich system," which had perhaps been overlooked, they said they had frequently been impressed by the need of engineering students being accommodated with courses of study which would enable them to get their practical training without the necessity of being banished from home influences for a continuous period of several years at a most critical time in their lives. If the practical and theoretical training could be so arranged that during the six summer months they worked in the shops while living in lodgings, and during the six winter months they took up theoretical study in the colleges, living at home and subject to good influences and affectionate surroundings, this home influence would be a source of great security, especially if the six months they worked in the shops were during the summer, when their spare time could be spent in outdoor pursuits. Unless courses of study could be arranged to alternate with periods of practical work, so that the young man avoided being banished from his home, he would clearly be placed at a disadvantage compared with those young men whose homes were in the manufacturing districts, such as Glasgow, Newcastle, or Birmingham. For these reasons the colleges, especially those in London, should endeavor to arrange their courses of study so as to conform to the social conditions indicated as desirable, and should arrange their engineering courses of study during the winter months.

Apprentice Adviser.

In the second place, attention was drawn to the desirability that in works some member of the staff should be looked upon as an adviser to the apprentices. It was clearly undesirable for an apprentice to be simply under the eye of the foreman, and those who had worked in the shops would know that it was almost impossible for him to obtain an interview with the heads of the firm. It would, therefore, be a very desirable thing, if in works, some gentleman could make it part of his business, as it were, to befriend the apprentices. He should be accessible at all times, and should make a point of interviewing each lad at least once in three months. He should also from time to time ascertain what progress was being made by those lads who attended evening classes, by periodical visits to the local technical schools. A record should be kept in a book, so that the heads of the firm could see at a glance the opinion formed of the various apprentices. It was a notorious fact that employers had often lost the services of capable men through being ignorant of the talent that had passed through their works.

Requirements of Works Training.

The title of a note by W. H. Allen was "The Requirements of Practical Training in Works, with the Necessary Complement of Scientific Study."

He said it was often asked, in the case of a student determining to go both to college and to works, which he should enter first. He would say, that the man who set himself the task of obtaining his degree before entering the works, stood a much better chance of securing a higher and more responsible position in life than the one who was trained in the reverse order. The former not only took a greater and more complete interest in the works and workshop life, but made the most of his time, and grasped ideas and their principles much more readily than the man who came to the works with merely a public-school training.

Study During Practical Training.

Another question frequently asked was, "How much study should a pupil undertake during the period of his practical training?" If a young man conscientiously did his duty from 6 o'clock in the morning until 6 in the evening, he would find that as much as his health could stand, without burdening it by further serious study at night. At the same time unless some attention was paid to the work which has been done at college, this part of his studies was apt to lose its freshness and interest for him, his attention being concentrated purely on his daily task to the exclusion of everything else. The author's custom had been to give lectures weekly, explainatory of the actual work being carried on in the shops, thus greatly increasing interest in and adding to the knowledge of the work being done.

Workshop Training Requirements.

As regards the requirements of workshop training, there seemed little doubt that a period of three years—the actual time depending on the previous education of the subject—including a year in the drawing office, should be spent in the works in a not too specialized manner; that was to say, it should cover work in some or all the branches of mechanical and electrical practice, which might be found in some of our better establishments. It would always be difficult, if not impossible, to lay down a plan for either scientific study or works apprenticeship which would suit all, and each individual case would require consideration on its merits. At any rate, whatever plan was adopted, would have to be very elastic as regards the arrangement of details. The tendency at present was to attach rather too much importance to the direct value of scientific study, as being the means of providing the student with certain mental tools for use in after-life, and too little to the development of the mental faculties generally, and the cultivation of a true scientific insight.

FOUNDRY PRACTICE AND EQUIPMENT

Practical Articles for Canadian Foundrymen and Pattern Makers, and News of Foundrymen's and Allied Associations. Contributions Invited.

By J. S. Van Cleve

DEFECTS IN GAS ENGINE CASTINGS.*

IT is said that the same method of molding prevails now that did when Solomon built the temple. This may be so, but I am very sure that King Solomon never made any water-jacketed gas engine cylinder castings. This is one way of saying that there has not been the same advance in foundry practice, as there has been in the demand made on the foundry. This may be true with respect to the majority of foundries, but a few which have specialized on complicated gas engine castings are getting very satisfactory results. For the past dozen years there has been a growing tendency to shift more and more of the responsibility upon the foundry, and those of us who have given special attention to this class of work have been kept very busy, devising ways and means to meet these requirements.

Pattern Requirements.

Gas engine castings must not only be true to pattern, but the iron must be homogeneous, and entirely free from interior as well as exterior defects. To obtain these results three things are necessary. First, a pattern properly designed to take care of the strain and shrinkage. Second, a proper mixture of iron, and third, workmanship. The foundry seldom has a chance to take care of the first item. The tendency is to let the pattern maker construct the patterns as he sees fit, and then to put it up to the foundry to produce the castings. Where it is possible, however, the pattern shop and the foundry should work hand in hand, with a view to not only getting good, true, sound castings, but with a view also to producing them at the least cost.

By a pattern properly designed, I mean more than the mere construction of a well built, nicely finished pattern. You must not only have the pattern built as well as it can be built, but careful study must be given the method of construction. Oftentimes patterns can be parted in various ways and at various places. Great care should be taken that the parting of a pattern is given proper consideration, because pattern makers use the easiest method for them rather than consider the best for making castings.

In intricate work where cores of irregular outline are necessary, driers, truly speaking, are a part of the pattern as well as gauge boxes in which to gauge the cores, therefore the gauge for setting the cores should be furnished the foundry, along with the pattern. Where such parts are necessary in order to produce accurate castings, and are not furnished by the customer, the foundry either has to construct them for the customer or at its own expense, and where the customer refuses to furnish these essential parts, such as drier patterns and gauges, the foundry is often tempted to handle the work by means of bedding the core, with invariably poor results.

Metal Mixture.

The second point, that of mixture, is a great deal like a patent medicine receipt. No foundry which has made a success of gas engine castings likes to tell another foundry how it is done. Our own experience has been that it was just as dangerous to make our iron too rich as too poor. A great deal depends upon the coke. Having once found a coke that will do the trick, stick to it, but never take a chance. Have every car analyzed. and refuse every car that does not come up to the mark. Buy your coke analyzed and then see that you get what you buy.

In addition to this, there is no doubt that some good results can be got with various kinds of dope, such as thermit and manganese, and there are certainly times when nothing else sems to meet the case. A few years ago this subject of mixture was one of minor importance in the foundry, as engine manufacturers seemed content with a grade of iron that would hold together, and with an engine that would run and sell. To-day, however, the successful engine builder is constantly striving to improve his engine and prolong its life, and great thought is given the mixture in the various castings. This is especially true of cylinders, heads, valves and pistons. The customer of to-day has also become enlightened on engine construction and is not altogether satisfied with a good looking, good running engine, but wants an engine that is made up of the best possible materials. In view of these facts, conditions in the foundry have changed so that the problem of making satisfactory mixtures is no longer the simple one that it was, but is now a subject of vital importance, and the foundry to-day that is not looking after this part of the work, with a view to bettering the conditions at all times, is losing ground in the engine field. To produce a clean casting with a strong fracture, a close grain free from internal shrinkage, and yet an iron that will machine freely, is what the foundry has to do, in order successfully to turn out good engine cylinder castings and like parts.

Foundry Problems.

In view of the various designs of engine cylinders, the foundry is often put up against many very difficult and expensive problems to solve which I feel safe in saying, none of you engine manufacturers fully appreciate, except perhaps those of you who have a foundry of your own. When you get a close grain iron, the foundry meeets with the troubles which are due to shrinkage, caused by uneven metal lines. For example, take a spark plug boss. This boss is surrounded by light jacket walls, and is generally marked by a boss on the outer side of the jacket. From this mark on the casting a solid plug of metal varying in size according to the size of cylinders, extends to and connects with the barrel wall.

Now this uneven distribution of metal which we realize is necessary causes the foundry no end of trouble. It is not only in this particular case that such troubles exist, but all such places on cylinder castings are apt to cause similar troubles if close grain iron is used. Hence, the necessity of extra care to bring about uniform cooling, which in the case of engine cylinder mixtures must be done by means of chills. A knowledge of the successful use of chills is a part of the work that is only gain-

*Read before the National Gas and Gasoline Engine Trades Association, Detroit, June 20, 1911.

OUR ADDRESS.

Many visitors to Toronto intending to call upon Canadian Machinery, take the most convenient method of getting our exact address—the telephone directory. Through an oversight on the part of the Telephone Company, the latest directory gives the wrong number—111 University Street. The street was recently renumbered, and the entrance to our office is now 143 University Avenue, just the centre of the next block north of the number given in the telephone directory.

ed by experience, and in many cases is of as much importance as, if not more so, than the mixture itself.

To prove this, you can take a pattern from a foundry which has been running on it successfully and put it in another foundry which is using the same analysis, and yet get very unsatisfactory results, if the second plant has not a full knowledge of the use of chills. In considering this statement, please bear in mind that the iron has to contain the same distribution of carbons. The mere comparison of silicon, sulphur, phosphorus and manganese is not what I base my statement on. Carbon is the life of the iron and should be given constant attention, for you can often take two mixtures that will run alike or so nearly alike in silicon, sulphur, phosphorus and manganese, that the slight difference would have no effect one way or the other, and yet find a vast difference in carbon contents, which will produce entirely different results in the casting. Therefore the study of design, and a knowledge of changes which take place in the irons while cooling, and the effect that this change has upon the casting, and a knowledge of how to overcome these effects, are essential to the production of what I have called a proper mixture.

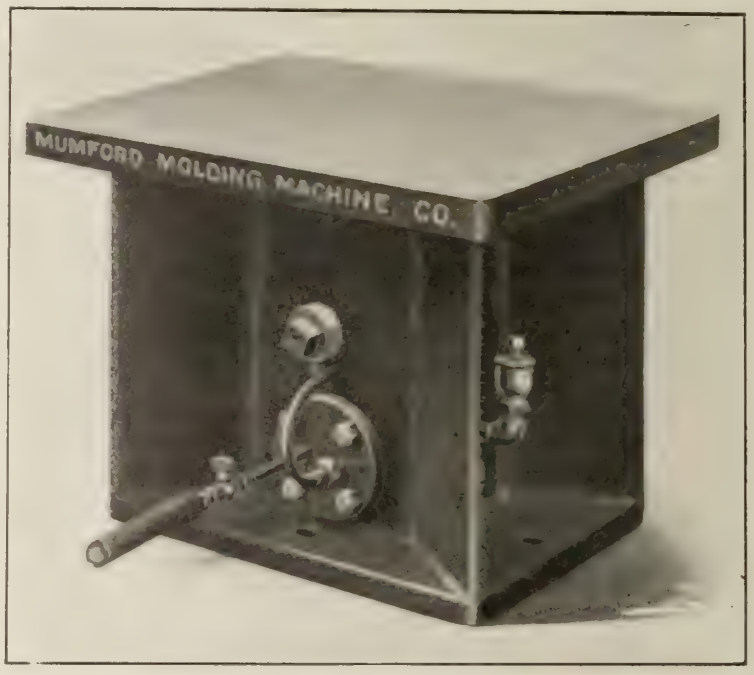
Foundry Rigging.

When you get to the third requirement, that of workmanship, you are into a very broad subject which could be almost indefinitely subdivided. The subject of minor foundry rigging is one of tremendous importance. Under this heading I have already mentioned gauges, core driers and patterns for chills. Skim gates and special flasks are scarcely less important. After foundry rigging, only second in importance, is the matter of proper gating.

It is a constant source of surprise to me, to see what a difference there is in the quality of castings when the molds are properly gated and when they are not, and how a very slight divergence or deflection may produce very far-reaching results. Break up an automobile cylinder casting, for example, and see what a difference there is in the constitution of the iron in that part of the walls where the mixture is allowed to pass continuously, and in those parts where it necessarily stagnates.

Workmanship.

Finally we come to the question of manual skill in the construction of the molds and cores and in the setting of the cores and securing of the molds. Gas engine castings, as they are made to-day, will not admit of the slightest degree of carelessness or indifference, and except in cases where the molders and core makers are making the same thing over and over again, it seems next to impossible to impress upon them the importance of absolute precision. The foremen and superintendents should be untiring in their efforts to impress this upon their men in the case of every new pattern, and should stay with the men until every possible precaution has been taken. Molders do not realize how much depends upon the form and style of chaplets used in different cases, nor do they exercise enough intelligence in the matter of venting. They must be shown these things in detail in each case, and then held strictly responsible for their work.



Losses by Manufacturers.

Gas engine manufacturers have suffered enormous losses in their castings from three causes principally. First, they trust their work to foundries who may be very skillful in other lines but have had no experience in gas engine castings. Second, by trying to buy their castings too close. No foundry which specializes on gas engine castings fails to realize that the incidental expenses in this line are much greater than in others, and yet being in competition with jobbing foundries, they are often compelled to do the work at prices which do not leave a fair margin of profit, and sometimes no profit at all. In such cases, it is only human nature to shirk somewhat, in the effort to economize. Again manufacturers of gas engines have suffered much loss from their insistence upon too great haste on the part of the foundry. Ample time should be provided for designing a pattern; and then ample time should be given the foundry to study it, prepare the rigging, and instruct the men. The policy of "rush the pattern makers" and then "rush the foundry" is a ruinous one.

There are many foundries thoroughly competent to produce the highest grade of gas engine castings, and these should be given a fair margin of profit and plenty of time to get out the work.

CORE BENCH JOLT-RAMMER.

A core bench jolt-ramming machine, built by the Mumford Molding Machine Co., Plainfield, N.J., is shown in the accompanying illustration. It may be placed on a concrete pier, iron post or wood foundation, and is especially adapted for ramming irregular cores. The machine is actuated by a knee valve under the bench, thereby permitting the operator to use both hands to manipulate the material and the core boxes.

Core Bench Jolt Rammer

While the capacity is 300 pounds, with 80 pounds air pressure, it can be used to advantage on small slender cores, which, together with the boxes, weigh only a few pounds.

Jolt Ramming Machines are generally associated with very large and deep molds, and only recently the facility of settling sand into deep pockets, and among the rods and wires of small cores on the core bench, has been appreciated. The valve consists of a plug of case-hardened machinery steel, having a 3-16-inch vertical stroke, and to all intents and purposes the construction is that of a valveless plunger. The economy in air, however, is superior to that of more elaborate valve mechanisms, used on jolt ramming machines. The size of table is 15×20 inches, and the diameter of the plunger is 3 inches. The finished shipping weight of the machine is 325 pounds.

MACHINE SHOP METHODS AND DEVICES

Unique Ways of Doing Things in the Machine Shop. Readers' Opinions Concerning Shop Practice. Data for Machinists. Contributions paid for.

MACHINING A DOG TOOTH CLUTCH.

By H. S. G., Toronto.

THE following is a "rig" that was used successfully to machine the inclined faces of a "dog-tooth" clutch on a shaper. A, Fig. 1, is a $\frac{7}{8}$ inch eye-bolt threaded for about 9 inches. B is a hand wheel from the scrap heap, drilled and tapped $\frac{7}{8}$ inch, with a groove $\frac{1}{2}$ x$\frac{1}{2}$ inch turned in the hub. D, Fig. 2, is a bar with a 1 inch hole to guide the screw, and E Fig. 2, is a bar with a fork to engage the groove in the hand-wheel hub. The prongs of the fork are rounded off as shown, to allow for the swing of the eye bolt.

The swivel table was mounted on the shaper and bolted down just tight enough to allow it to swing without shake. The clutch to be machined was clamped down concentrically on it, and the eye-bolt connected to the corner of the swivel table at C, Fig. 1; the carriage being set, so that the tool passed through the centre line of the clutch. The clutch was marked-off from a template, and as the tool was fed down to the work, the swivel table was swung by the hand-wheel. In machining a long tooth, the work might have to be done in two parts by running the hand wheel as far as possible in one direction, then running it back, and re-setting the clutch on the table to finish the rest of the cut.

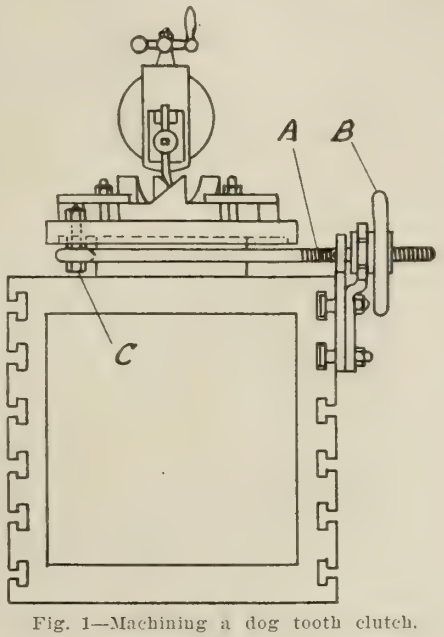


Fig. 1—Machining a dog tooth clutch.

AN AIR HOIST DEVICE.

By G. T. R., Toronto.

The top cylinder covers of air hoists are frequently damaged, due to the piston striking them, as a result of careless operation. Trouble like this may be easily prevented by the use of a light coil spring arranged as shown in the cut. A washer about 3 inch diameter should be placed above and below the spring, the coils of the latter being of $\frac{1}{4}$ or 5-16 inch steel, depending on the size of hoist and air pressure. This simple device costs little, and may prevent damage with its accompanying annoying delays for repairs.

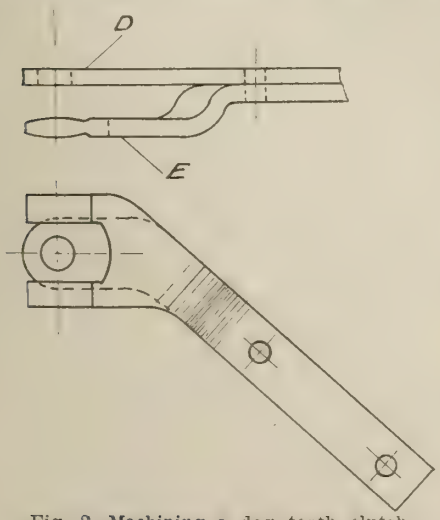

Fig. 2—Machining a dog tooth clutch.

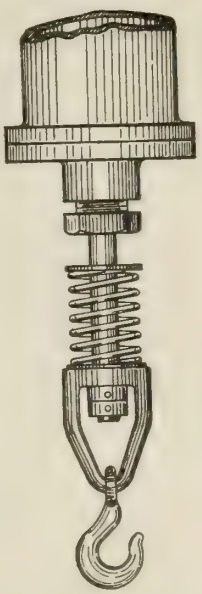
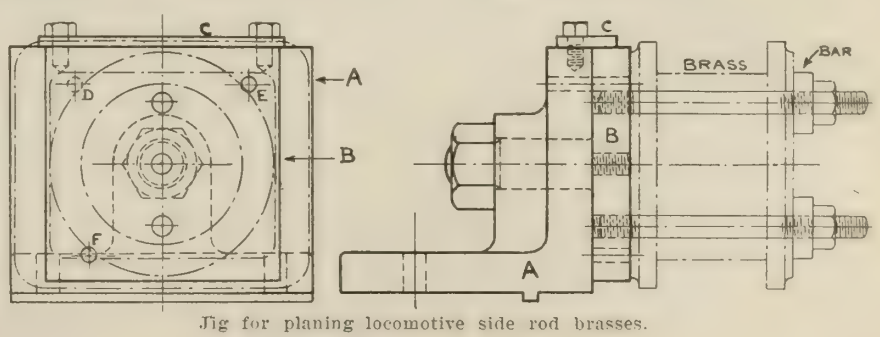


JIG FOR LOCOMOTIVE SIDE ROD BRASSES.

By L.S.R., Winnipeg.

The cut shows the usual form of jig for planing the rod-fit, on locomotive side-rod or main-rod brasses.



A is an angle bracket, bolted to the table of the planer or shaper. The top edge is machined parallel with the base, and a planed strip. C, is bolted to it by studs or set screws. B is a square block, having at its centre, a round shank which fits snugly into a corresponding hole in A, and is clamped in place by the nut at the back.

One edge of B is brought in line with the top edge of the angle plate, A, so that the plate C lies evenly on both. The brass is then bolted to the face of B by means of the long studs and bars shown, and is centred and roughly levelled. The top edge is now planed. Afterwards, the plate C is removed, the large nut slackened, the block B revolved through 90 degrees and the plate C replaced. Another edge of the brass is planed next, and so on for all four sides.

Air hoist device.

In cases where one end has to be planed taper to fit the adjusting wedge, the strip C, is removed. The hole D, is in the angle plate, while holes E and F are in the block B. E and F, are so located, that when one or other of them is brought opposite hole D, and a pin inserted, the top or bottom edge of the brass is at the correct angle for planing the required taper.

Jig for planing locomotive side rod brasses.

TWO USEFUL TUBE CUTTERS.

By J. Harcourt, Toronto.

TWO tube cutters for locomotive boiler tubes are here described and illustrated. Fig. 1 shows a cutter for 2-inch tubes, and is an extremely handy tool. The body is made to fit into the tube, and has a hole 11-16 inch square, in which the cutter slides. The spindle and jaw for driving the tool are solid with one another, the former having a short cylindrical projection at one end, and ¼-inch out of centre with the spindle. This projection engages with a slot across the body of the cutter, and moves the latter up and down in the square hole, when the jaw is turned to right or left.

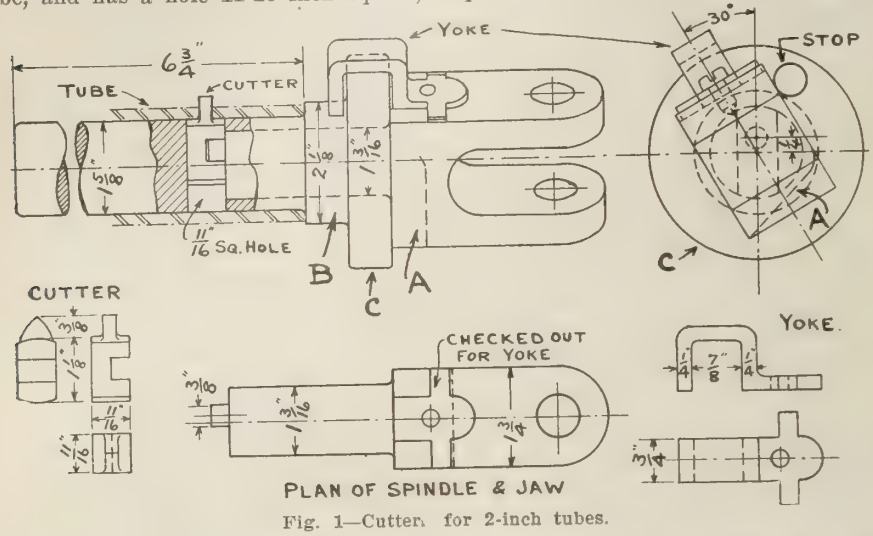


Fig. 1—Cutters for 2-inch tubes.

Having brought the cutter to the bottom of its stroke, the tool is inserted in the tube and the jaw turned to the right, thereby raising the cutter, and so piercing the tube. When the cutter is in this position, the side of the jaw is bearing against a stop, shown in the end view, and on the motion being continued to the right the tube is sheared all round. The strain is taken by the stop, which consists of a stud projecting about ½-inch. The bottom side of the jaw has a tapered groove, A, ⅝-inch wide, which enables it to be turned back to the left sufficiently to bring the cutter point inside the tube again, and allow the tool to be withdrawn. The yoke withdraws the body of the tool along with the jaw and spindle. To do this, some force is necessary, therefore the yoke is recessed into the top of the jaw for a depth of ⅛-inch to take the shear off the small screw that holds it in place.

This cutter was sketched in the G.T.R. roundhouse at Toronto, and differs from the usual form in the yoke and the position of the stop. As used in the C.P.R. shops and elsewhere, there is a slot in the shoulder B, extending half way round the circumference; the stop being screwed into the spindle, and working from end to end of the slot. By this means, the yoke and the larger diameter C, are dispensed with.

It will be noted that with the above cutter only about 1½ revolutions of the jaw are required to cut each tube.

It may be operated by air motor or ratchet wrench. A stout bar is rigged up across the smoke box front and the motor or ratchet connected up to the jaw of the cutter by a series of rods having universal and telescope joints enabling any tube to be reached without shifting the motor.

3 in. Tube Cutter.

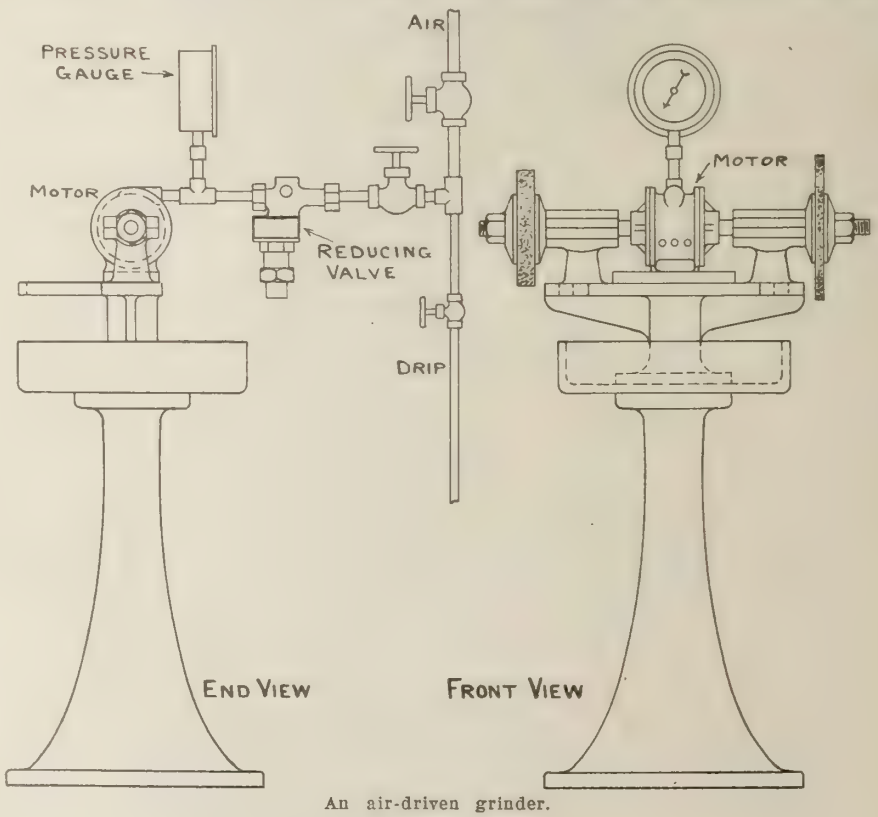

Fig. 2 shows another G. T. R. tube cutter as used at Toronto for cutting out the 3-inch arch tubes from locomotive fire boxes. It is made from a piece of extra heavy hydraulic pipe. The cutter wheel is carried in a jaw piece, which slides between two guides, and is wedged outwards through the tube by blows on the end of the shank. The whole apparatus is revolved by hand, through a long wrench on the squared end of the cap. When the tube has been cut, the wedge is easily drawn back by hand, the flat spring at once bringing the cutter wheel within the tube and allowing the tool to be withdrawn. The water space between the back head of the boiler and the door plate of the firebox varies on different classes of boilers; therefore a loose collar is clamped on the cutter to form a depth gauge, ensuring all tubes being cut off a uniform distance inside the firebox.

AN AIR-DRIVEN GRINDER.

The small double grinder shown in the attached cut was sketched in the Frog and Switch shop of the G. T. R. at Toronto. It is driven by a small air turbine or motor, mounted on the shaft, between two emery wheels. A reducing valve on the air line brings the pressure down to about 40 pounds per square inch, the pressure gauge being mounted where it can be easily read.

It is not claimed that this is a highly economical method of driving an emery wheel, but where, as in this case, there is no belt or electric drive available, it serves the purpose admirably.

For the sake of clearness, the emery wheels have been omitted in the end view. An idea of the scale of the drawing may be gathered from the fact that the thinner of the two wheels is 10 inches diameter, and that the centre of the spindle is 39 inches from the floor.

An air-driven grinder.

BORING A CYLINDER ON ENGINE LATHE.

By B.F.W., Toronto.

In the machine shop of B. F. Williams, Toronto, the problem presented itself, of how best to bore several cylinders on order. Their diameter was 8½ inches, their length 30 inches, and the only available machine for boring them was an engine lathe swinging 21 inches. Each cylinder being, of course, much too heavy to chuck in a lathe of this size, the latter was converted into a boring mill in the usual manner, by rigging up a boring bar and strapping the cylinder to the carriage, as clearly shown in the cut.

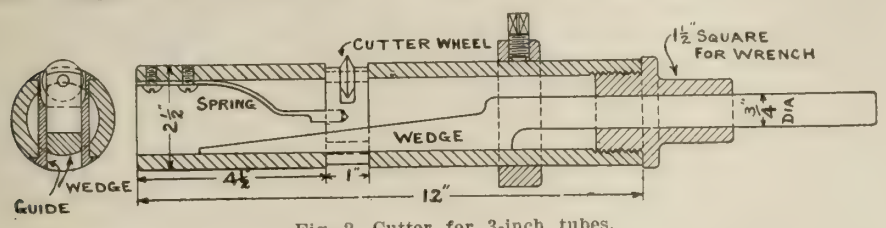

Fig. 2—Cutter for 3-inch tubes.

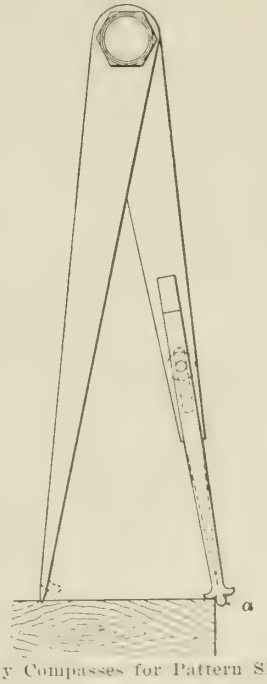
If the steady rest supporting the end of the boring bar had been mounted on the lathe bed, the carriage would not have had sufficient travel to do the job; therefore it was necessary to mount it on a short length of channel iron, attached to the underside of the bed and supported by two struts as shown. The lead screw had three bearings, one at each end and one behind the apron. To get the necessary length of travel for the carriage, the bearing at the tailstock end had to be removed, but the remaining two bearings were found to give ample support to the screw.

A piece of 2 15-16 inch shafting formed the boring bar, and as this had a sunk keyway already cut for a considerable portion of its length, it came in handy. An old damaged spur wheel, turned down to form the tool holder, was keyed to the shaft about 33 inches from the headstock end.

As will be seen from the cut, the cylinder had two feet, set close to each end. These were supported on two hard wood blocks, G, cut to fit the Vee ing cut. A first class job was the outcome.

Referring to the cuts, A is the boring bar; B the tool holder; C the tool; D the steady rest; E the piece of channel iron to which the steady rest is bolted; F the cylinder; G, the hard wood blocks; H, the wood packing between cylinder and carriage; J, the bolts holding down cylinder to carriage by means of the angles K; L. the packing strips between cylinder feet and carriage preventing motion of cylinder sideways; and M, the four jaw chuck.

While this method of boring a cylinder is not new, the process is an interesting one, in view of the "home-made" nature of much of the apparatus used.

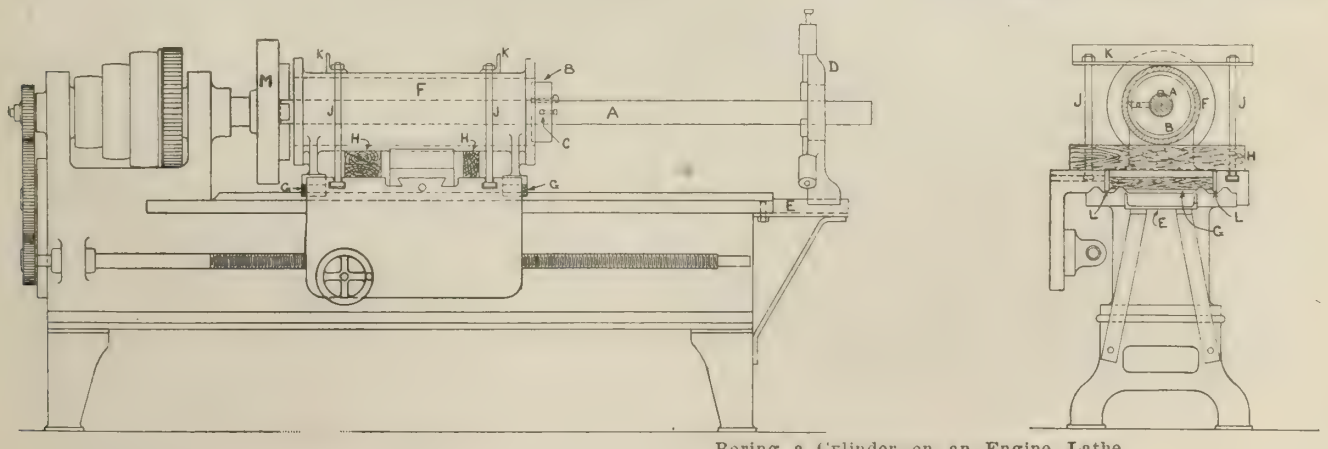


HANDY COMPASSES FOR THE PATTERN SHOP.

By a Patternmaker.

The accompanying illustration shows a handy and convenient tool for patternmakers' use. As a combined caliper and marking gage, it has proved itself most popular in the pattern shop where it was devised. Some patternmakers never use a hermaphrodite caliper, while others have the regular caliper which may be purchased in tool supply stores. Others again have home-made calipers. I employ this caliper when the work requires and very often I use it in preference to a marking gage.

The caliper that I describe in this article is remodeled from a standard make of calipers. It differs from the standard caliper in the reversing of the legs, as shown by the full lines, while the standard make is shown in the dotted lines.



The dotted leg is drawn out straight, finished and tempered. Don't forget the temper. That makes its worth double. If you expect to use this or any other tool for the purpose of cutting or parting (which is the purpose of this tool) of the wood, the cutter must have a proper temper. The scratch leg is shown by the dotted line. I have removed this one and substituted the leg as shown in the full lines.

Handy Compasses for Pattern Shop.

The sketch is clear and complete and really requires no explanation. The stock is about 1-16 inch and the end at a is finished in the form of a ball.

For marking dimensions on turned work, this is a superior tool.—Castings.

Boring a Cylinder on an Engine Lathe.

DEVELOPMENTS IN MACHINERY

A Record of New and Improved Machinery Tending Towards Higher Quality and Economical Production in the Machine Shop, Blacksmith Shop or Planing Mill.

IMPROVED BENCH TOOL GRINDER.

THE accompanying half-tone shows an improved design of standard bench tool grinder recently put on the market by the Ford-Smith Machine Co., Hamilton, Ont. The usefulness of this type of grinder has long been demonstrated, and the present example has a special feature in the additional wheel on the outside, to take care of small drills or such other tools as cannot be conveniently ground on the larger wheel. This outside wheel can be readily changed for any special shape, should occasion arise.

Another feature is the hand hole for cleaning out, seen in front. This does away with the necessity for removing the hood and wheel spindle as in the older designs. An unusually large water pot is provided, and careful attention has been given to the guards and tray. The larger wheel is 12 inches diameter by 2 inches wide, and the smaller wheel 8 inches by ½ inch. The advantage of wet over dry grinding, providing sufficient water is available, is generally admitted, both on account of the time saved, the better finish on the tool, and the absence of liability to draw the temper.

This machine is known as the "12 inch Rapid" and is suitable for distribution around the larger shops at any point required. It is equally well adapted to the requirements of smaller shops, having the desired tendency to put the tool grinding on the right basis, at a minimum of expense. The bench space occupied is only 22 by 18 inches. Fast and loose pulleys, 5 inches diameter for a 3 inch belt, are provided, also an extra heavy spindle running in self-oiling bearings. If desired, the machine can be direct driven by electric motor on the spindle.

24-INCH SINGLE SURFACER.

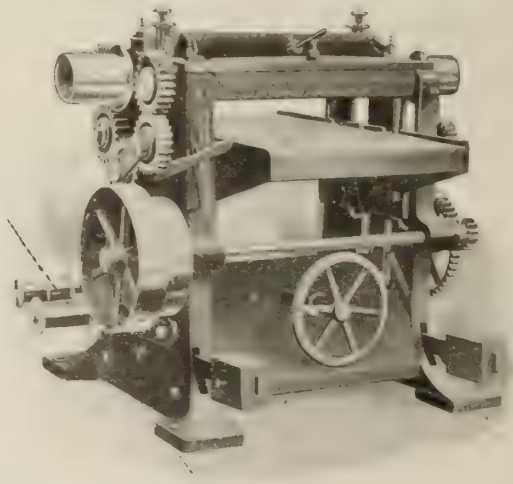
THE wood surfacer illustrated, is built by the Valley City Machine Works, Grand Rapids, Mich., and will plane stock 24¼ inches wide by 8 inches thick. It is a double belted machine, as may be seen from the cut, which shows the surfacer with its gear covers removed.

The frame is designed to give ample strength, and has a large surface for the bed, the base being planed, so as to give a uniform bearing on the floor.

The main bed is raised and lowered by the hand wheel seen in front; is cast in one piece, with adjustment for wear by wedge and screw. The centre bed is held by four bolts, and can be taken out when required for trueing up. An index is located on the main frame, to indicate quickly the position of the table for a given thickness of stock.

A single cylinder made from steel forgings runs in long self-oiling bearings at 4,500 r.p.m. It carries two 5 by 5 inch driving pulleys, and is fitted with two knives. The four gear rolls are power driven, the feed gears being held together by a yoke and link, so that they cannot get out of mesh. There are two rates of feed. The upper feed rolls are adjusted by means of a wedge and screw, and are held down by heavy coil springs, thus enabling the operator to feed stock of varying thicknesses at one time. The weight of the machine is 2,200 pounds.

FOOTE-BURT HIGH DUTY DRILL.

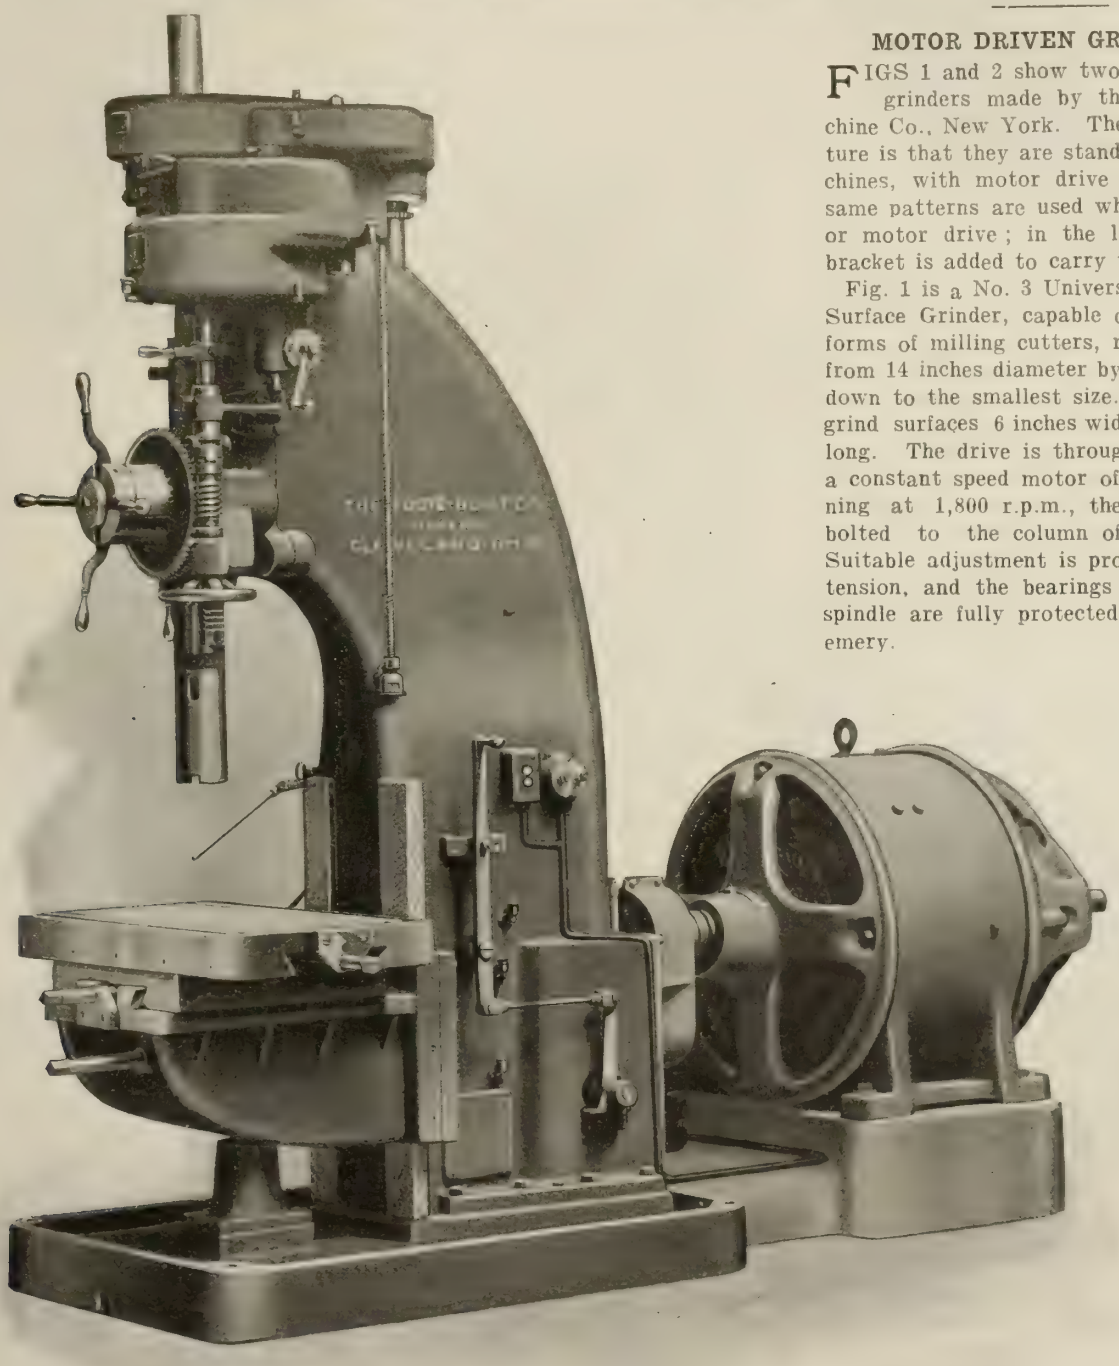


THE 36 inch swing, high duty drill press which we illustrate, was built by the Foote-Burt Co., Cleveland, Ohio, and operated at the equipment exhibit in connection with the Atlantic City conventions of the A.R.M.M. and M.C.B. Associations last month. Some extremely interesting drilling tests were there made on it, with "Paragon" high speed drills manufactured by the Cleveland Twist Drill Co., Cleveland.

General Description.

No special equipment was provided for this test, it being simply a standard machine, with a high speed drill capacity, up to 3½ inches dia. in solid steel. Nine changes of geared feed are provided, any one of which is instantly available without stopping. The power feed is provided with adjustable automatic and hand stops, while the hand feed is accomplished by means of worm and

Ford-Smith Bench Tool Grinder.



Valley City Wood Surfacer.

worm gearing. The quick traverse of the spindle in either direction, is attained through a spider hand wheel located in front of the machine, which with either the "in or out" movement of any or all of the handles, engages or disengages same.

The table is of the bracket knee type, and has, a large square lock-bearing surface on the upright to which it is securely gibbed. It is further supported and elevated by a square thread telescopic jack screw, located underneath, and slightly back of the spindle, to permit boring bars or other tools passing through the table. The motor drive consists of a 20 h.p. four-to-one variable speed motor, geared direct with a two-to-one reduction. Back gears give a further gear of four-to-one, and make possible, spindle speeds varying from 37½ to 600 r.p.m.

A compound table can be fitted, if desired, and is not an attachment to the regular table, but consists of an entirely new knee. This compound table has a longitudinal movement of 14 inches and a cross movement of 8 inches. The distance from centre of spindle to face of column is 18 inches, and the maximum distance from the table to the nose of the spindle is 31½ inches with the standard table, or 5¾ inches less with the compound. The length of the power feed is 16 inches, and the net weight of the machine, 7,000 pounds.

The table under the heading, "Recent Drilling Records," shows the remarkable results obtained when carrying out the already-mentioned test. With one exception the drills used were the Cleveland Twist Drill Co.'s "Paragon" flat twisted high speed type. It will be noted that the 1¼ inch size, drilled cast iron at the rate of 57½ inches per minute constituting in this respect the highest drilling speed on record.—See page 211.

FOOTE-BURT HIGH DUTY DRILL PRESS.

MOTOR DRIVEN GRINDERS.

FIGS 1 and 2 show two motor driven grinders made by the Garvin Machine Co., New York. Their special feature is that they are standard stock machines, with motor drive applied. The same patterns are used whether for belt or motor drive; in the latter case, a bracket is added to carry the motor.

Fig. 1 is a No. 3 Universal Cutter and Surface Grinder, capable of grinding all forms of milling cutters, ranging in size from 14 inches diameter by 6 inches face, down to the smallest size. It will also grind surfaces 6 inches wide by 9½ inches long. The drive is through a belt from a constant speed motor of 1-6 h.p., running at 1,800 r.p.m., the motor being bolted to the column of the machine. Suitable adjustment is provided for belt tension, and the bearings of the main spindle are fully protected from floating emery.

The weight of this machine is 435 pounds.

Fig. 2 shows a surface grinder driven in like manner. The motor is mounted

Fig. 1—Garvin No. 3 Universal cutter and surface grinder.

on two steel arms bolted to the side of the column, on which is the track for motor adjustment, to maintain correct tension in the lower belt. The upper looped belt, driving to the spindle has also a compensating tightening device. The motor is of the constant speed type, ½ h.p., running at 1,650 r.p.m., and the machine will grind surfaces 7 inches wide by 9½ inches long and of thickness from ⅛ to 6 inches. The total weight is 450 pounds.

When such machines are located in isolated places, and a live shaft drive is not available, an easily applied motor drive is of special value. Further, being easily portable, they can be set down in any position.

GARVIN PLAIN MILLING MACHINE.

We illustrate herewith the No. 22 plain milling machine, built by the Garvin Machine Co., New York. It is the most powerful and largest capacity machine they make, and has been designed for continuous hard work; all non-essential parts having been dispensed with.

The spindle has a No. 11 Brown and Sharpe taper hole with driving slot, and runs in adjustable bronze boxes. The drive is by means of a 12-inch cone and 4-inch belt, the gear ratio being 5¼ to 1.

From Fig. 1 a new departure will be noted. One side of the machine is closed; so that the arm and spindle bearings are joined rigidly together and to the body of the machine, thus securing great solidity and freedom from vibration. The feed is driven from a spindle on the back shaft, by throwing over the eccentric seen in Fig. 3. The feed ranges from 1-200 to ¼-inch per turn of spindle

The table is driven by a non-rotating screw and a rotary steel nut, shown in Fig. 4, both screw and nut being hardened. The hand feed is operated by hand wheel and spiral gears running in oil, while the rotary feed nut is driven by a worm gear and worm running in oil.

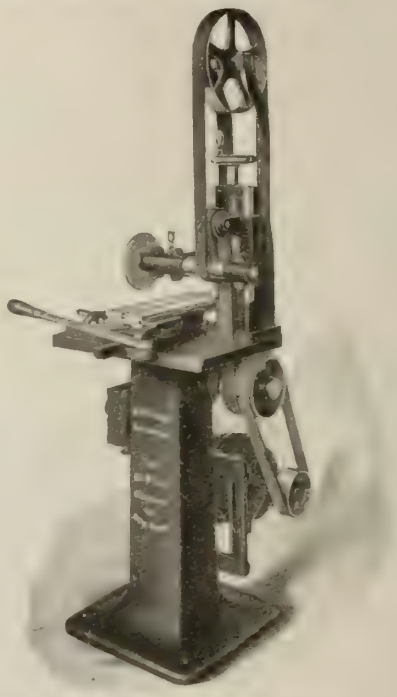


Fig. 2—Garvin surface grinder.

The feed box is built into the saddle, so that the stresses are taken up in the most direct manner with the smallest number of joints. The saddle has micrometer adjustment in and out. The

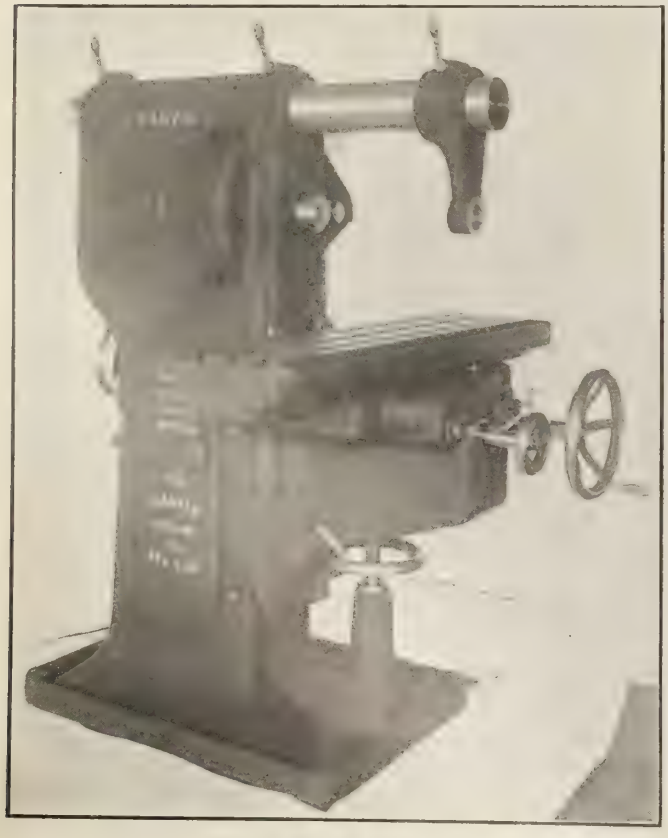

Fig. 1—Garvin plain miller.

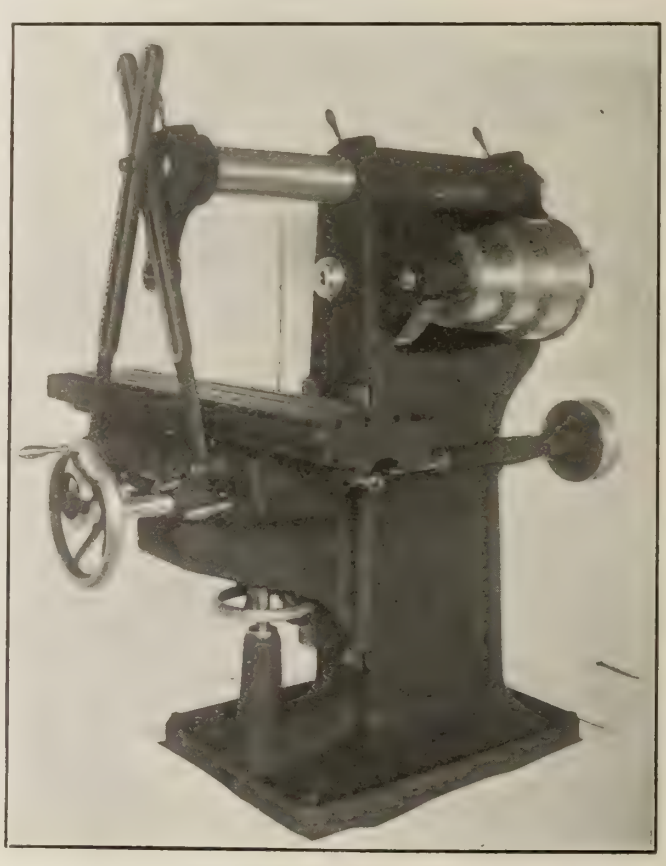

Fig. 2—Garvin plain miller.

knee has the Garvin closed top construction, and is raised by micrometer handwheel and a screw, the latter not passing through the floor. The arm is large and the braces shown in Fig. 2 connect it with the saddle, leaving the yoke free for adjustment to suit the arbor and position of cutter.

HEAVY DUTY DRILL PRESS.

THE 24 inch heavy duty drill press which we illustrate, has lately been re-designed by the makers, the Colburn Machine Tool Co., Franklin, Pa. The machine has a capacity for drilling 3 inch holes in solid steel with high speed drills running at speeds and feeds recommended by the drill makers.

Constructional Details.

In the former design, the drill had a right angle drive, necessitating the use of quarter turn belts, when a number of machines were set in a row and driven from one line shaft. This has been changed, and the main driving shaft in the speed box, on which is mounted the driving pulley, is now parallel with the line shaft. No countershaft is required, all changes of speed and feed being obtained through positive gearing, by means of levers conveniently situated within easy reach of the operator, standing in front of the machine, Fig. 2.

The speed box, of entirely new design, is mounted on a substantial knee at the rear of the main column. Eight changes of speed can be obtained through sliding gears and positive clutches, operated by means of levers, E and Z, Fig. 1. All gears in the speed box are of steel, running in an oil bath, and the corners of the teeth are beveled where they slide together. A target, I, on the top of the speed box, shows which gears are engaged. Four of the speed changes similar to the changes with a selective transmission on an automobile, are made by means of lever E, and a set of back gears operated by lever Z, increases the number of speeds to eight.

The machine drives through a friction clutch pulley, operated by means of lever G. Being a high-speed drill press, with the gears running at a high rate of speed, it is impossible to make the speed changes when driven by the regular clutch pulley, on account of the severe impact caused by too sudden engagement of gears and clutches. To overcome this, an auxiliary friction clutch is interposed between the main friction pulley and the gears in the speed box. This auxiliary friction is operated by means of lever F, and by its use, the gears are made to turn very slowly and the different speed changes can be made without jar or shock.

Operating Features.

The different speeds and feeds, and the combination by which they are obtained, are shown on a speed and feed index plate attached to the feed box in plain sight, and the operation of changing either speeds or feeds is most simple. To illustrate: for 45 revolutions of spindle per minute, the positions are: Lever Z at slow, and the rod Y at A. The machine should be at rest when making changes. The operator first takes hold of lever Z with his left hand and throws it in the direction marked slow. This is the back gear lever and operates one gear and a positive clutch.

If the gears have come to rest so that the teeth will engage, it will not be necessary to revolve them; but if not, the operator takes hold of lever F with his right hand and pulls gently. This operates the auxiliary friction clutch and causes the gears to turn slowly, until they can be brought into engagement.

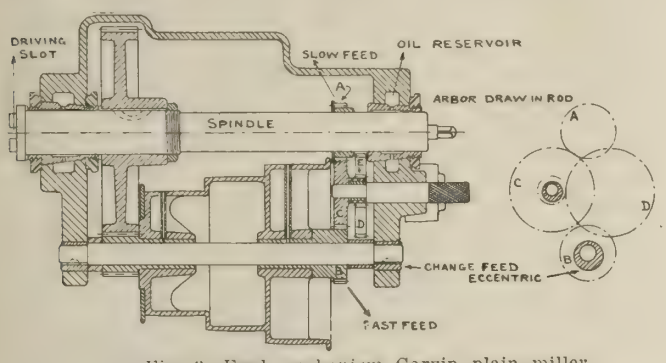

Fig. 3—Feed mechanism Garvin plain miller.

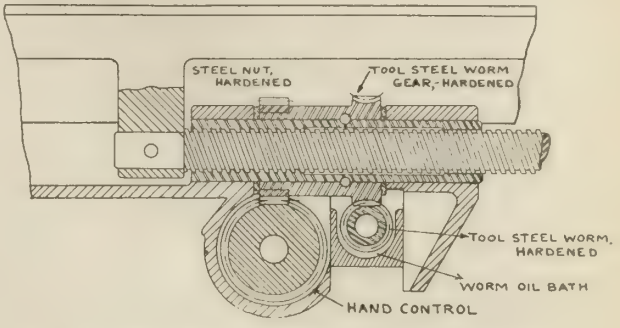

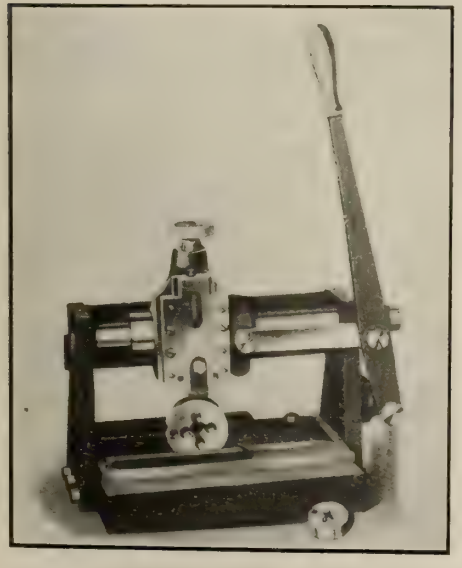

Fig. 4—Table driving screw, Garvin plain miller.

MARKING MACHINE.

IN shops manufacturing taps, dies, drills, or in any plant where letters or figures have to be stamped on the product, a marking machine such as we illustrate is almost indispensable. Besides making a much more uniform impression than can be obtained with the usual steel stamps, the work can be done much quicker on a machine.

The pressure is obtained through a powerful toggle lever, and the head of the machine is provided with means for quick vertical adjustment, to allow for varying thicknesses of stock being stamped. There is also a stop arrangement to regulate the horizontal movement. This machine has a capacity of 1,800 pieces per hour, and is adapted for straight stamps on round work, and circular stamps on flat work.

The makers are the Remington Tool and Machine Co., Boston, Mass.

Remington marking press.

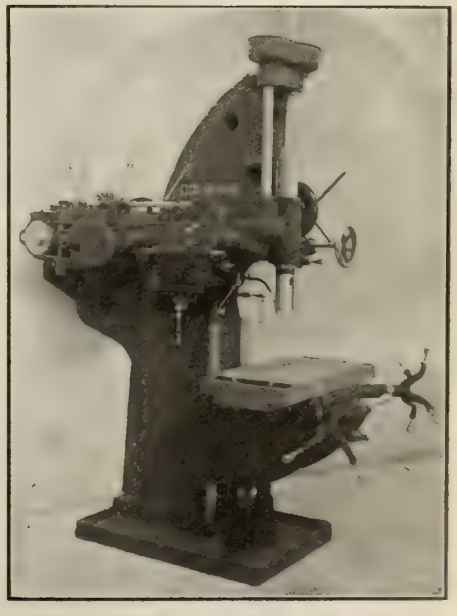

Fig. 1—Colburn heavy duty drill press.

The speed at which the gears are turned by the auxiliary clutch can be regulated by the pressure on the lever F, and thus any danger of damage to the mechanism is entirely eliminated.

The position of the two rods Y, is indicated by pointers traveling across the face of a target having the letters B, A, C, D. The front rod Y, has a pointer which indicates its two positions C and D, while the rear rod Y has another pointer, indicating its two positions B and A.

The lever E has a pin which engages slots in the two rods Y, Y. By sliding the lever backwards in its bearing H, the pin enters the slot in the rear rod Y, and by sliding the lever forward, the pin enters the slot in the front rod Y. Only one of the rods can be moved at one time, and the pin cannot be moved from one rod to the other, until both are in neutral positions; this being accomplished by a strip of metal fastened rigidly between the two rods, with a single slot through which the pin will just pass. To change the pin from one rod Y to the other, it is always necessary to bring the slots in both rods opposite the slot in the center strip. With the rods in these positions, the sliding gears are not in mesh. Consequently there is no chance for the gears to fight, and the device is fool proof.

If the gears do not slide together in the position in which they come to rest, the operator will take hold of lever F and with a slight pressure, gently revolve them, when they can by means of be thrown into engagement by means of lever E. The actual sliding of the gears is accomplished by right and left movements of the lever E, while changing of the pin which moves the rods Y, Y, from one to the other, is accomplished by sliding the lever through its bearing H. Often after the machine has been stopped, the gears or clutches can be engaged without using the auxiliary clutch lever F, but whenever the teeth do not engage, a slight pressure on this lever causes them to turn into the correct position.

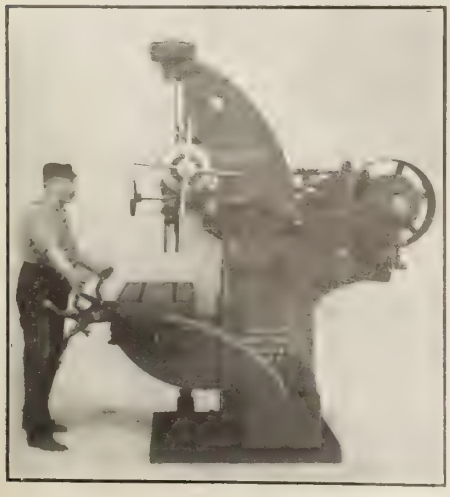

Fig. 2—Colburn heavy duty drill press.

Speed and Feed Changes.

The feeds, of which there are six, are obtained by means of the pull rod X operating the back gears, and the pull rod W operating the dive key. To change the feeds on the high speeds, it is advisable to stop the machine and proceed as for changing speeds, but when running on the slow speeds, the machine need not be stopped to change the feeds. The whole operation of speed and feed changing is extremely simple and is quickly made. By looking at the index plate, the operator can see at a glance just what to do to get any desired speed or feed, or he can tell at just what speed or feed the machine is running, by noting the positions of the levers and rods and comparing them with the index plate.

"CANADIAN FOUNDRYMAN."

"Canadian Foundryman," devoted to the foundry, patternmaking, polishing and plating interests, contains each month, bright helpful articles and news concerning the doings and achievements of manufacturers and operators in their respective fields. Readers of Canadian Machinery will find it of invaluable assistance in acquiring a knowledge of kindred trades, at low cost.

Spindle and Drive Equipment.

The spindle is of forged high carbon steel, the thrust being taken on ball thrust bearings. It has a No. 5 Morse taper at the bottom and a total travel of 16 inches. Direct feed on spindle is through a worm gear carrying a graduated dial, reading in thirty-seconds of an inch. The graduations being about $\frac{1}{8}$ inch apart, a finer measurement than 1-32 inch can be made by reading between them. This dial has an adjustable pawl, which can be set to automatically trip the feed at any point up to 14 inches travel of the spindle. The feed can also be tripped by hand. In addition to the above graduated feed dial, there is another safety trip which automatically stops the feed when the spindle has reached its lowest position, thus preventing possible accident on account of feeding down too far.

The machine is built with either the standard bracket type of table as shown in Fig. 3, or with a compound table as

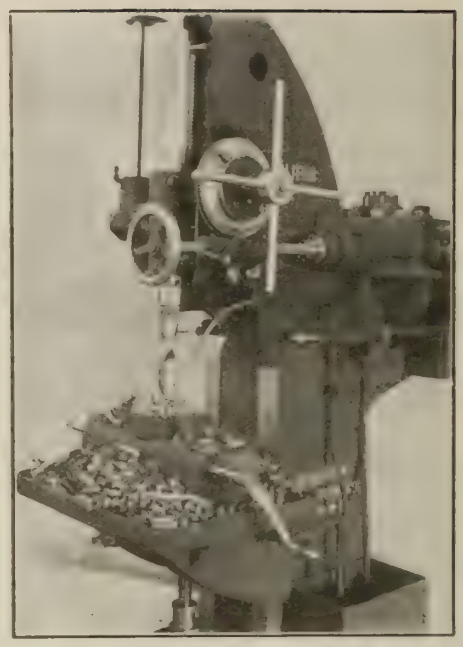

Fig. 3—Colburn heavy duty drill press.

in Figs. 1 and 2. Both tables have a telescopic elevating screw which eliminates the necessity of making a hole through the floor. Special chucks or other fixtures may be mounted upon either type of table. In Fig. 3 is seen a two jaw universal chuck, specially adapted for holding gear blank forgings and similar work. The jaws are made detachable and special styles can be fitted for irregular shaped pieces. The illustration shows a 2½ inch high speed drill, boring a steel gear blank at a feed of 4 inches per minute.

To adapt the machine for motor drive a special bed plate having an extension for the motor is provided. The motor is located directly under the clutch pulley, to which it is belted. The clutch pulley of course allows the machine to be stopped and started without stopping the motor. A constant speed motor is used, of from 10 to 20 h.p., depending on the work to be performed.

JAPANESE RAILROADS.

The manager of the Japan Rolling Stock Co. (Mihon Sharyo Kaisha), recently stated that a large amount of rolling stock will be required in Japan in the near future, as a result of the extension of the government railways, and it is estimated that by 1923, 500 locomotives, 750 passenger coaches, and 9,300 freight cars will be placed on these lines, necessitating an aggregate expenditure of about $12,500,000 to $15,000,000. In addition, considerable quantities of stock will be required for the lines built, and will be constructed by private companies, of which 17 or 18 were organized last year.

Vol. VII. August, 1911 No. 8

TIME LIMIT FOR TENDERS.

IN our view, the period allowed from the date of publication, or receipt of tender forms by the contractor or his representative, is in most cases totally inadequate, and seems in addition to bear no proportion whatever to the amount of contract price involved. Surely in such matters, opportunity should be given to go carefully into the requirements called for, by all desirous of submitting a quotation, as only thereby will fair competition have its rightful stimulus, and the best possible equipment be secured at the best possible price.

Much of the discussions on higher efficiency hinge on the workman's pay roll, his output in relation to it, and but little is heard of inefficiency otherwise. In the broad outlook, large opportunity awaits these efficiency experts' attention, as in this particular phase of "open tender," we believe betterment and all-round benefit to be derivable. Doubtless, most concerns in whose particular lines these large contracts lie, are so organized as to be able to figure closely and rapidly; still even these, we think, would perhaps feel more secure in their price, and reap a larger profit, were the time allowance extended.

THE MECHANICS' EDUCATION.

A CAREFUL perusal of the contents of the current issue of "Canadian Machinery," will convince the most sceptical, as to the earnestness of desire and effort put forth by manufacturers and others concerned, in the direction of providing sound, practical and technical training to all willing to avail themselves of it.

At the recent Conference on "The Education of Engineers," held in London, England, (the first section of a report of which appears in this number) it is abundantly clear that employers are fully alive to the question, and are actively propagating the work. "Education of Engineers" is a term used in its widest sense, and, therefore, includes among the others, all engaged in Machinery and Machine Tool manufacture. A feature of much importance at this Conference, was the opportunity afforded, what might be termed the purely educational interests, to get into close touch with employers of large engineering works. There has always been a more or less want of community of interest existing between these two sections, in the mechanical development of those under their care, and we believe much good is likely to result from the personal interchange of ideas.

Men or youths who aim to make progress in their chosen profession of Mechanical Engineering, should take advantage of every form of education that will better equip them, and the University, Technical School, Works Educational Schemes, (where such exist) will all be found powerful helps to the daily shop practice. In Canada, there are already large, well-equipped colleges, covering to a large extent the higher branches of an engineer's education, and the steps being taken to supplement those by establishing Technical Schools in all industrial centres, will enable an increased number to take advantage of, and benefit by their combined services.

CONVEYING YOUR IDEA TO ANOTHER.

THROUGH the lack of the knowledge necessary to convey their idea or invention to paper, in writing or drawing, many men have been denied the reward which would otherwise have come to them. It is noticeable that lack of capacity in the former respect, causes mistrust of those who could put the ideas in intelligent form for them, and this circumstance of itself is sufficient justification for the plea in favor of more particular attention being paid to the acquirement of at least a fair measure of mechanical drawing and sketching.

Most men, imbued with a liking for their work, have dreamings of improvements in the methods adopted and the means employed; and who, more than the operator, has a better opportunity of seeing them assume the form of practical possibility. This being so, should it not be the earnest endeavor of every machinist, and the younger generation of them especially, to so equip themselves, that whatever they divine as an advance and improvement on existing practice, may be committed to paper at their own hands.

The ability to put one's ideas on paper, has the further advantage that more effect can be given to the particular scheme being developed, because of the concentration obtainable. Sketching machinery details and afterwards drawing same to some scale, will familiarize those who practice it with such all-important points as the securing of necessary dimensions and views, from which another may be able to work. Those deficient in the art of drawing and sketching, and who persist on that account in withholding the privilege of committal by another of their ideas to paper, are more numerous, perhaps, than we might at first sight credit, and being so, mechanical progress is held back, on account of these men, in course of time, dying off, and taking what was of value to all, with them.

WRITING TO TRADE PAPERS.

Zeal is generated and stimulated to know and find out more, by writing trade or business articles, and what a man acquires in this way is invaluable, because no matter how much of his knowledge he gives away to others in his writings, his own store becomes no less, but as a matter of fact, does really increase.

Mechanical Drawing and Sketching for Machinists*

By B. P.

A Series of Progressive Lessons Designed to Familiarize Mechanics With the Use of the Apparatus Necessary to Make Simple Drawings, to Encourage them to Realize How Important a Factor it is of Their Equipment, as Well as Being a Profitable Pastime.

BEFORE going further into the making of detail drawings, it will be necessary for us to consider how an object may be represented by a series of views, bearing a definite relation to one another. Take for instance, a common brick. This has three dimensions, length, breadth, depth, therefore the drawing will consist of such views as will give all necessary information.

Different Views and Locations.

Fig. 1 shows a drawing of the brick, which is 9 inches long, 4½ inches wide,

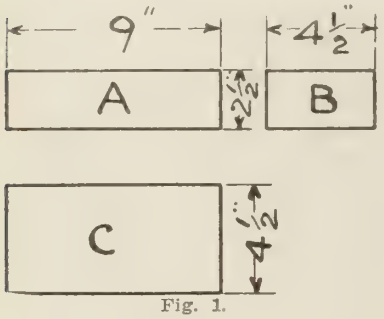

Fig. 1.

and 2½ inches thick. A is known as the front elevation, and is a view of the brick as it would appear in the face of a wall. B is a view looking at one end, and is known as the end elevation. C is a view looking down upon the top of the brick, and is known as the plan or plan view.

Fig. 2 is a perspective drawing of the same object, and from the letters, it can be easily seen which face of the brick is represented in each of the three views of Fig. 1. Thus to obtain the end elevation B, we turn the object through an angle of 90 degrees to the right; similarly, the plan view is obtained by turning it through 90 degrees downwards. This is the simplest system, although there are others in common use. For instance, some draftsmen would place the plan, C, above A, instead of below it, and would place the end elevation B to the left of A, instead of to the right. In this instruction course we will adopt what to us appears the simplest plan —that first described.

The question may be asked, why three views as in Fig. 1, when all the dimensions can be clearly shown in one view as Fig. 2? A little consideration, or better still, a little experience, will show that a perspective drawing would be too inconvenient a method of representing a complicated casting, or in fact, anything but a simple rectilinear object. Consequently, the method shown in Fig. 1 is adopted and is known as the method of orthographic projection, or projection by straight lines. We shall learn more of this later on.

Number of Views.

Referring again to Fig. 1, the front elevation A, shows us that the length of the brick is 9 inches, its thickness 2½ inches, while the end elevation B, shows that its width is 4½ inches. We have, therefore, learned all three dimensions from two views. The plan C is required nevertheless, as it tells us that the corners are square, whereas they might be rounded for all we learn from A and B.

It must not be supposed that three views are always sufficient or necessary, to clearly show the construction of any article. Frequently it is necessary or useful to show four or five views, to enable some complicated object to be more easily understood. Mechanical drawing is a language by means of which the draftsman conveys his ideas to the mechanic, and as in other languages, the more complex the subject, the greater the number of words (views) needed to describe it.

Dotted lines tend to make a drawing confusing and difficult to read, and should not be used more than absolutely necessary, although it is of course impossible to eliminate them altogether. Such things as cylinders and hollow castings, or forgings of all kinds are usually shown most clearly by making one or more views known as "sectional views." A sectional view is that which would appear were the object cut through a certain plane.

Explanatory Example.

In making a drawing of a cast-iron tank, with outside dimensions, 24 inches long, 20 inches wide and 14 inches deep, let us assume that the body metal is everywhere 1 inch thick, and that 9 inches from one end, there a partition ¾ inch thick, extending to within 2 inches of the tank top, and having a 2 inch hole on the longitudinal centre line, 7 inches down from the top. A scale of three inches to one foot, or one-quarter

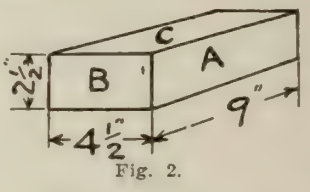

Fig. 2.

full size, will be a suitable scale for the drawing.

Starting with the front elevation, the first step will be to construct by use of tee square and set square, a parallelogram equal to the outside length and depth of the tank. Next, dot in the lines representing the thickness of ends, bottom and partition. The partition, be it remembered, is ¾ inch thick, and stops

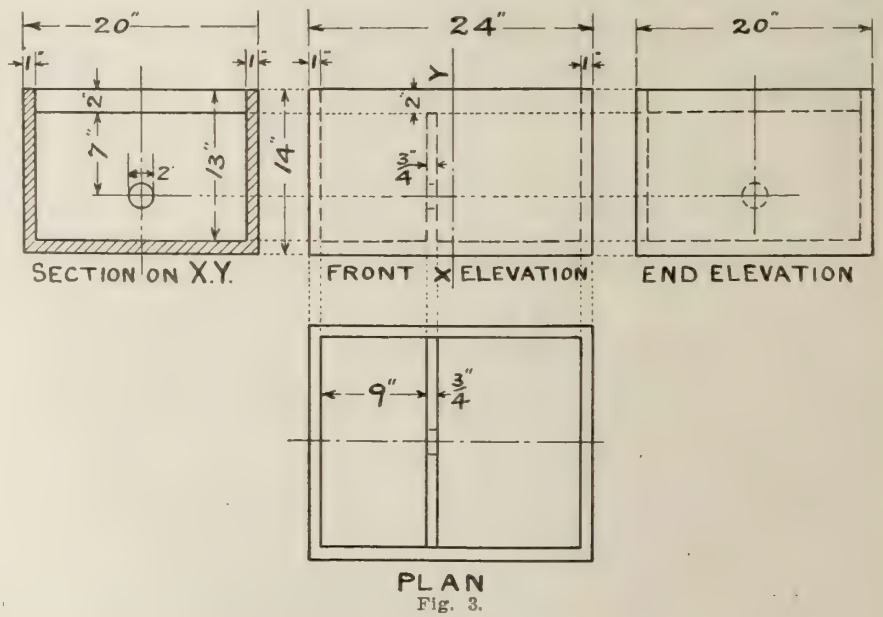

Fig. 3.

*Fifth of a series of an instruction course.

short 2 inches from the tank top. Seven inches below the top of the partition, draw a short horizontal line to represent the centre line of the hole required there, and one inch on either side of it draw a dotted line through the partition representing the edges of the 2 inch hole. This completes the front elevation. We next proceed to draw the plan immediately below it, and here instead of measuring off the length of the tank again, you simply bring the working edge of the tee square about 6 inches below the bottom line of the front elevation and with your set square, produce the end lines of the tank downwards

Draw the lines for the thickness of the ends and the partition in like manner. Now draw a horizontal line about one inch below the lowest line in the front elevation, to represent one side of the tank. Next, set off a distance of 20 inches, along one of the end lines and through the point thus obtained, draw another horizontal line to show the other side of the tank. Inside these two lines, draw two more lines representing the 1 inch thickness of the sides. The plan is now complete, except for the two inch hole in the partition, and which is put on the centre line of the plan as already described, when drawing the front elevation. The height of the end elevation is projected across from that of the front, by means of the tee square, and a vertical centre line is drawn, on each side of which half the width of the tank is set off.

A section on XY, is shown to the left, chiefly as an example of what a sectional view is.

Assume the tank to be cut in two at the line XY (front elevation), then an end view at the line of section would appear as shown. In future lessons, the usefulness of sectional views in eliminating dotted lines, and enabling one to form clearer ideas of the construction of hollow pieces, will be further considered.

AMERICAN FACTORIES IN CANADA.

In the absence of government statistics showing the number of American factories which have established branches in Canada, the Montreal Star, after a careful canvass, reports a list of no less than 184 with a combined estimated capital of $233,000,000.

The products of these branch factories include, among other things, agricultural implements, electrical machinery, malleable and gray iron castings, gas engines, saws, and tools, conveying and mining machinery, railway iron and steel work, chains, automobiles, horseshoes and nails, transmission machinery, stoves, lumber, barrels, boxes, office furniture, couches, folding beds, silverware, paints, oils, varnishes, printing inks, fountain pens, cereals, confectionery, self-sealers, silk thread, paper, roofing paper, gum, gas, fly paper, chemicals.

Some of these are well known and their coming has been widely announced. The city of Hamilton alone has 15 branches, while in Montreal there are 19, and in Toronto 63. There are no statistics showing the number of persons employed, but it is clear there are many thousands. Two factories in Hamilton alone employ 5,000.

WORKMEN'S COMPENSATION.

The Court of King's Bench in appeal, has rendered judgment in a case under the Workmen's Compensation Act, which will probably have considerable effect in shaping the views that judges will take in applying the measure to cases coming before them. The law in question is a new one, and applies to the cases of employer and employe within limits and on principles not otherwise recognized. These are fairly set out in the judgment to which reference is made.

A young man was engaged to do certain work for a quarry company. In moving from one part of the works to another, a day or two after his engagement, he loitered at a place where he had no occasion to be. He was warned by the foreman in charge of operations to move, and had hardly retorted that he was in no danger, when an accident happened and he sustained such injuries that death followed. Suit was brought by a relative for compensation on the ground that the deceased was her sole support. There was no apparent question as to what were the facts. The contributory carelessness or neglect of the victim, was not a bar to the claim made upon the employer. The liability of the latter was held to exist when there was a relationship between the work of the employe and the accident which injured him.

To quote the words of Mr. Justice Archambeault, speaking for the majority of the court, "To come under the act it appears * * * unnecessary that the workman should be at a precise spot assigned to him. From the moment one of the cogwheels of the machinery of which, so to speak, he is a part, causes an accident, the accident happens in the course of the work, or professional risk, and the employer is liable." After accepting this view the court had only to decide on the amount of damages it would award. The law fixes $1,000 as the minimum in case of death, with $2,000 as the maximum, but it gives the court power to reduce the amount, where the mishap is due to the inexcusable fault of the workman, and to increase the allowance where there has been inexcusable fault by the employer.

The court under this authority, fixed $500 as the sum to be paid to the plaintiff, indicating that the victim of the accident was responsible, and, to a certain extent, that his employer was not. This judgment the Court of King's Bench upholds.

The advantage of the Compensation Act to the employer is presumed to lie in the fact that by it, so far as it applies to his employes, his liability is definitely fixed. As this case illustrates, it may be larger than was generally anticipated. A law on similiar lines in Great Britain has worked to considerably increase the demands upon employers of labor, and though liability underwriters have increased their rates for insurance, not many of them have found their business profitable. It would appear that the same experience will be noted in Quebec.

TECHNICAL EDUCATION COMMISSION.

Gilbert M. Murray, the manufacturers' representative on the Royal Commission on technical education and industrial training, has returned from Europe, having left his colleagues at Zurich, Switzerland.

The commissioners went first to London, England; then to Manchester, Leeds, Halifax, Bradford, Glasgow, Edinburgh, Hull, and Leicester. Crossing to Germany, they visited Berlin and Munich, and then began their tour of Switzerland. Zurich was the first stop for observation, and the end of Mr. Murray's European itinerary. The other commissioners, however, were to make further investigation elsewhere in Germany.

A trip to the United States will be made before the report of the commission is completed.

The Smart-Turner Machine Co., Hamilton, have recently filled the following orders:—The Tug Salvor, of Port Arthur, one pump; the Wells Pattern & Model Works, Toronto, side suction centrifugal pump; Gunns, Ltd., West Toronto, side suction centrifugal pump; the Rogers Cheese Co., Frankford, Ont., Duplex pump; the Cronmiller-White Brewing & Malting Co., Port Colborne, Duplex double acting power pump; the Monarch Knitting Co., St. Thomas, automatic feed pump and receiver; the University Power House, Toronto, Duplex pot valve pump; the Canadian Colored Cotton Co., Hamilton, Duplex pump; Canada Coating Mills, Georgetown, single vacuum pump; the International Harvester Co., Hamilton, side suction centrifugal pump; L. J. Looby, Owen Sound, side suction centrifugal pump; the Acheson Oildag Co., Sarnia, couple of pumps; the Burrill Lumber Co., Three Rivers, P.Q., Duplex boiler feed pump.

Boiler Design, Construction, Operation, Repairing and Inspection

By H. S. Jeffery

The Various Points in Connection With Boiler Practice Will be Clearly Taken up In This Series. The First Article Dealt With the Boiler Shell, Including Repairing, Factor of Safety, Hydrostatic Test and Number of Courses. The Series Will be a Complete Text Book on the Subject of Boilers, and Should be Preserved for Reference.

Bracing.

All boilers, especially tubular boilers, are so constructed that a part is self-supporting. The shell is self-supporting because the force acting upon it tends to maintain a circular form. It is also true that the flues of a tubular boiler are subjected to pressure at all points, but

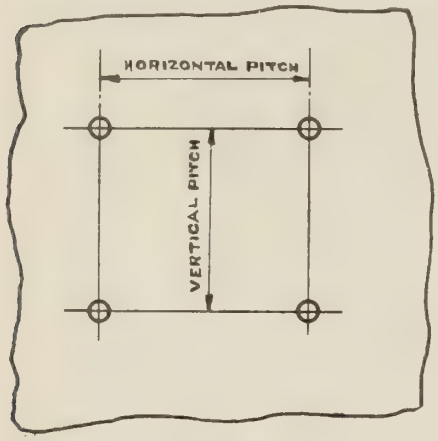

Fig. 34.

the pressure on the shell is internal and that on the flues external, except in the case of water-tube boilers, where the flues are subject to internal pressure.

Parts of the boiler that are not self-supporting must be stayed or braced in a manner which will prevent deformation or bulging when the boiler is in service. There are many ways of bracing boiler parts; the water space of locomotive and similar types of boilers is stayed with staybolts. With staybolts, attention must be given to three things: (1) the area supported. (2) The size of the staybolt. (3) The thickness of the plate supported.

The area is computed by authorities differently. If the staybolts are pitched 4-inch centres, the area would be 16 square inches, and all authorities so figure, but if they are pitched 3¾ x 4 ins., most authorities would figure the area to be supported as 4x4 equals 16 square inches. This rule requires staybolts to be distributed in such manner that the distance between the vertical and horizontal rows will be as nearly uniform as practicable—that is to say, if the staybolts were pitched, say 3½x5 inches, the area supposed to be supported by each staybolt would be equal to 5 squared, or 25 square inches. The area is usually computed by the following formula:

$$\frac{C \times T^2}{D} = P$$

Where:

C=Constant (See note).

T=Thickness of plate in sixteenth of an inch.

P=Working pressure.

D=Greatest pitch of staybolts.

Note: The constant depends upon the thickness of plate and also the authority.

In selecting the size of staybolt, one of the first things to consider is the thickness of plate which the staybolt is to support. Now the staybolt may be sufficiently large to support the area allotted to it and the pitch may be about the usual pitch, 4 inches, yet the plate may be so light that the pitch is excessive. This is illustrated by the arrangement, Fig. 34. Assuming the constant to be 110 and pitch 4 inches, the allowable working pressure for a ¼-inch plate would be, $\frac{110 \times 16}{16} = 110$ pounds, and for a ⅜-inch plate, $\frac{110 \times 36}{16} = 247.5$ pounds.

It will be seen by the above that the ⅜-inch plate, while only ⅛-inch heavier, is allowed a much greater working pressure. Further, the size of the staybolt has not been considered—the working pressure has been determined only. The staybolt diameter depends upon the allowable stress per square inch. Since staybolts are subjected to both a direct pull and a vibratory stress, their factor of safety is considerably higher than that of the boiler shell. Again, the threads of the staybolt open avenues for the starting of cracks and as the least area eaten away by corrosion reduces their strength materially, the usual stress allowed is 6,000 pounds per square inch.

With the ¼-inch plate in the foregoing example, the load on the staybolt will be: Area × pressure or 16×110= 1,760 pounds. Dividing by the allowable stress per square inch, the area required will be:

$$\frac{1{,}760}{6{,}000} = .293 \text{ square inch.}$$

The diameter of the staybolt at the root of the thread is then:

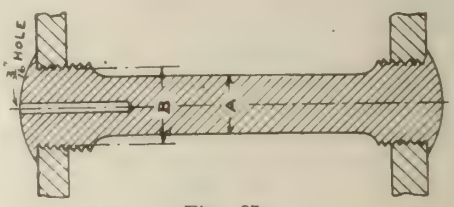

Fig. 35.

$$\frac{.293}{\sqrt{.7854}} = .614, \text{ say } \tfrac{5}{8}\text{-in. diameter.}$$

All staybolts are not threaded their entire length—some are "skinned" out as indicated in Fig. 35. This staybolt has a small 3-16-inch hole in one end, and is a practice used extensively with locomotive boilers, the purpose being to give an alarm by escaping steam when fracture takes place. As staybolts nearly always break at or near the outer wrapper sheet, the tell-tale hole is installed in the end attached to said sheets.

When a staybolt is so "skinned" and the tell-tale hole installed, the area at diameter A, Fig. 35, is ascertained, also the area at diameter B less the area of the tell-tale hole. The lesser of the two is the net area of the staybolt. Usually staybolts are "skinned" out sufficiently that the least area is that from the diameter A.

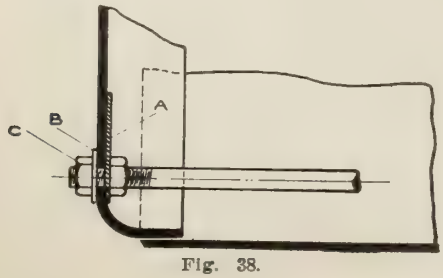

Fig. 38.

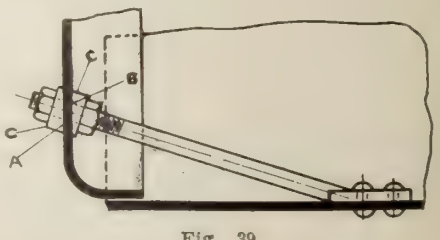

Fig. 39.

It is important to note that staybolts do not always support both sheets to which they are attached. The furnace of an upright boiler is stayed; and the stays are by necessity attached to the shell sheets. Staybolts should be placed at right angles to the surface they support, or as near as practicable. If the staybolt is supporting a curved surface, it should be placed as radiating from the apex of the curved surface. Curved surfaces which are not self-supporting are stayed the same as flat surfaces. The fact that the furnace of an upright boiler would successfully resist 30 pounds steam pressure without staying is not taken into consideration if the boiler is to be constructed and stayed for 100 pounds steam pressure, and the size of the staybolts, their pitch and the thickness of the plate is computed without regard to the curved surface.

When bracing the segment of a boiler, the braces cannot be spaced uniformly. This is illustrated in Fig. 36, where it will be noted that there are three rows of braces and the pitch is 5 by 8¾ inches. Unlike staybolts, the area supported by a brace is computed as the minimum pitch times the maximum by most authorities, and in this instance: 5×8¾ equals 43¾ square inches. Other

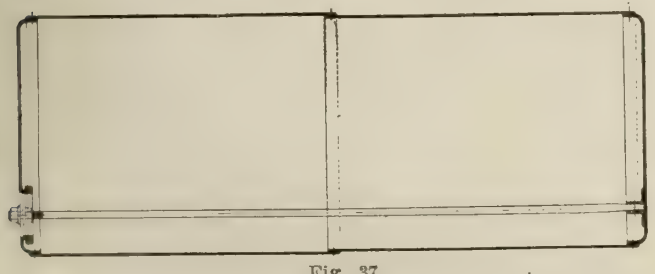

Fig. 37.

authorities used a split-the-difference method as follows:

$$\frac{5^2 \times 8.75^2}{2} = 50.78 \text{ square inches.}$$

The rule used for the rivets is the same as for the staybolts. Example: The distance between the rows of braces, Fig. 36, is 5 inches, while the pitch of the rivets is 4 and 4¾ inches, respectively. This makes three different rivet pitches, 4, 4¾ and 5 inches, respectively. Practically all authorities would figure the area supported by the rivet as: 5×5 equals 25 square inches. It will be seen that to determine the size of brace, necessitates knowing just what method the authority having jurisdiction requires. The rivets which hold the brace to the boiler head are treated as far as calculations are concerned the same as staybolts, the area supported by a rivet being calculated as above.

Direct and Indirect Braces.

Direct braces are to be preferred to indirect, yet it is impossible with some boilers to apply direct braces throughout. Diagonal braces should not be placed at an angle greater than 20 degrees, and with a three-course tubular boiler, it is good practice to have some of the diagonal braces attached to the centre course. The diagonal brace length multiplied by the area of a direct brace required to support the surface, and divided by the length of a line drawn at right angles to the surface supported and to the palm of the diagonal brace, gives the diagonal brace area. Formula:

$$\frac{S \times L}{B} = A.$$

S=Sectional area of direct stay.
L=Length of diagonal in inches.
A=Sectional area of diagonal brace.
B=Length of line drawn at right angles to boiler head or surface supported to palm of brace.

Example: The diameter of the direct brace is 1 inch, length of diagonal stay 60 inches, line drawn at right angles, boiler head to palm of brace 48 inches. What is the sectional area of indirect brace?

$$\frac{.7854 \times 60}{48} = .981 \text{ square inch, say } 1\tfrac{1}{8} \text{ in.}$$

In Fig. 36, the manhole below the tubes permits entrance into the boiler for the purpose of inspecting, cleaning, and repairing; and necessitates bracing the heads there. This is accomplished in several ways. The front head with the flanged hole is supported by same, yet many require the ring A to be shrunk on. A method of staying, is to apply angle irons to the rear head and fit 2 end-to-end stays as indicated in Fig. 37. Some stay the flues, attaching a liner to the rear head instead of angle iron, and fitting 2 end-to-end stays as indicated in Fig. 38.

The method, Fig. 37, is superior to that in Fig. 38, for the reason that the liner A, Fig. 38, makes a double thickness of plate at a part of the boiler in contact with hot gases. In Fig. 37, the water is in direct contact with the greater portion of the flue head. Further, the nut C and washer B, Fig. 38, will hardly be indirectly cooled by the water in the boiler and will soon burn off. One difficulty with the angle irons, Fig. 37, is that the space for the eye of the end-to-end stay becomes clogged with mud. The manhole in the front head permits this to be watched, however, so there will be no accumulation to the extent that the boiler head will be over-heated and deformation take place.

A brace used to some extent for the segment above the tubes, but rarely below the tubes, is shown in Fig. 39. It is not a good brace as the hole in the flue head is made larger than the brace by at least ¼-inch and when the brace is installed there are openings above and below as indicated by the letters A and B. The bevelled washer C does not bear fairly against the plate at every point, and although the spaces A and B

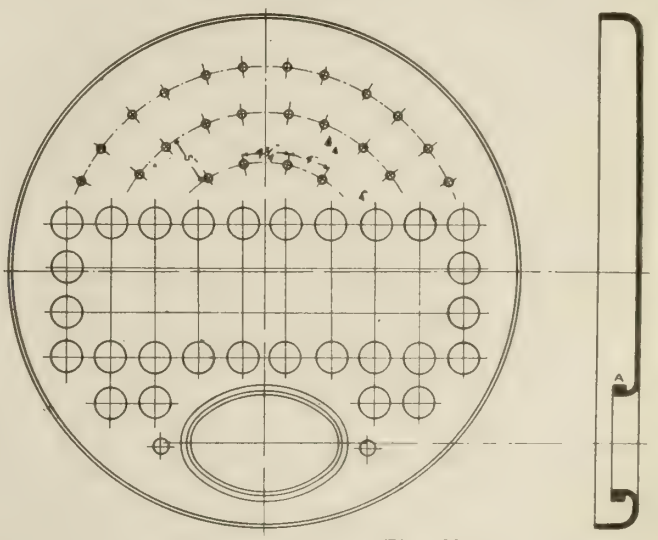

Fig. 36.

are "packed," the packing in time works out and the brace leaks.

A man, like a knife or a saw, can have too little temper as well as too much. We should not be soft enough to batter and turn easily, nor hard enough to crumble or break. It frequently behooves one to try and fit his temper to the services he wishes to render.

In the August issue of MacLean's Magazine is a contribution in which the writer claims that Earl Grey is right in attacking us—although he should attack more than Canada—and that at the same time the Public Schools are right in saying that they are not solely to blame. The trouble is from a much deeper source. The Canadian people should try to find the cure. This article hints at it.

SYSTEMATIC BUSINESS MANAGEMENT

Practical Articles for Managers, Superintendents, and Foremen, to Assist in Carrying on the Business Economically and Efficiently.

THE HANDLING OF MEN.

THE following abstract from a letter of G. O. Griffith, of Fort Flagler, to a contemporary will be found of interest to our readers.

"In the management of men to get the best results, the man in charge must have their respect. To get this, he must treat them as men who are in no way inferior to him, except in the matter of work. There are men working in lower positions than they should be, because some one higher up does not appreciate their work, and does not therefore give them their just dues. Every chief should watch and study his men, and when one shows that he is competent and deserving of advancement, the chief should give him what he deserves, and show no favoritism.

"Fair treatment will get better results than unjust treatment. Men dislike a person who is always 'cussing' and 'grouchy' with them, and they will not do as good work when he is away as they would otherwise. Of course, there are men who will not benefit by good treatment, and with such a man, he has either to be got rid of, or be made understand that he will have to do as he is required.

"Perhaps nothing will make a man slight his work so much when he gets the chance, as abusive language. Most men like to have their work praised occasionally."

THE SMALL MACHINE SHOP.

By H.S.G., Toronto.

IN these days of keen business competition, when success depends so much upon a careful study of system and economy, it is surprising how many of the smaller machine shops are operated with little regard to those details which make for smooth running and efficiency. Of course, the average small shop, besides manufacturing some special line of machinery, has much of its time occupied with a variety of repairs and is therefore not in a position to give much effect to the matter of improved equipment. Every tool has to be a "Jack of all trades," still much may be gained by giving thought to the handling of the employes.

Efficiency of the Employe.

Try to keep each man as much as possible to one machine, as the advantages are many; for each will develop speed at his work, will take a pride in keeping his machine in good condition, and will have at hand the necessary bolts and clamps, so avoiding loss of time and temper.

Do not disregard the suggestions of a reliable workman with regard to the purchase of equipment. If he repeatedly complains of a lack of some appliance to handle his job, it is safe to say, that the resultant saving of time and increase of business would soon repay the outlay on new apparatus.

Keep the tool-room locked, and insist on a check for every tool issued. When system is relaxed, the men help themselves indiscriminately, and not only keep tools out longer than necessary, but cause the number of broken drills, taps, and reamers to mount up at an alarming rate.

Do not let the apprentices pick up everything for themselves. It is easier to acquire bad habits than good and besides, a careful supervision of the apprentices, will save a lot of damage to equipment, and a little encouragement will bring out all the good there is in the young hand.

Consider the comfort of the workers, and provide a room where they can eat their dinners in comfort and cleanliness. Give them proper lavatories, and realise the impossibility of getting good work out of discontented workmen.

"THE POWER HOUSE."

The August issue of "The Power House" will contain a full account of the C.A.S.E. Convention, held at Stratford, Ont., in the latter part of July. All interested in Power Plant Development and Operation will find much to attract them in that special Number, and arrangements should be made to become subscribers and secure a copy.

SAFETY DEVICES ON ELECTRIC CRANES.

OF late years the speeds of electric cranes have been increased considerably, yet the provision of adequate safety devices to prevent over-winding and over-traveling has not always received the attention it merits, although in other applications of electrical power, manufacturers have devoted a considerable amount of time and money to the problem of placing on the market automatic and "fool-proof" devices, designed to secure immunity from accident due to errors of judgment on the part of the workman.

Electrical Equipment.

The electrical equipment of a crane usually includes a main switch and fuses, a branch fuse for each motor circuit, together with a rheostatic controller for each motor, no provision being made to prevent the attendant from switching on the current when the controllers are not in their "off" positions, as is generally done with the most ordinary motor control gear. In several instances, however, the main switch and fuses have been replaced by ordinary, overload circuit breakers, which, in order to be effective in preventing accidents through mistakes of this character, should be of the free-handle type. There is, however, a decided objection to the use of ordinary circuit breakers for this class of work, on account of the fact that very often the controller handles are so operated that a momentary large rush of current is produced, which though not of sufficient duration to do any harm to the electrical equipment is of sufficient magnitude to cause the circuit breaker to open and bring the crane to a standstill. The resulting delays may be only trifling, but in the aggregate they are responsible for serious loss of time, and in foundries and steel works are the cause of other and more serious losses. To avoid this trouble, circuit breakers, when provided, are generally rendered inoperative except under very heavy overloads, and so cease to afford any real protection against overloads of smaller magnitude, which may still be of sufficient duration to have serious effects on the remainder of the equipment.

In a system of control designed to overcome these troubles, the crane control panel is equipped with a main circuit breaker, provided with a low voltage release attachment, and instead of a branch fuse for each motor circuit, there is an overload relay with a time limit device, by means of which a dangerous overload on any particular motor, of sufficient duration to cause overheating or excessive sparking, may be entirely prevented. In addition, each motor controller is electrically interlocked with the circuit breaker, in such a manner that, after it has once been opened by the application of an overload or through any other cause, it can be closed again only when the controllers are re-

turned to their "off" positions and all resistance inserted in the motor circuits. It is thus rendered impossible for the attendants to make any mistake in the proper sequence of operations; and in case of failure of the supply voltage through any cause, there is no possibility of an accident happening through the current being switched on again unexpectedly.

The Need for Control Urgent.

With the high traveling and hoisting speeds now in use, the need for suitable safety devices for limiting the hoisting and traveling motions has become urgent, but so far has met with little response, beyond the occasional addition of a limit switch to the hoisting motion to prevent over-winding, and rarely also, to the traversing motion of overhead cranes to prevent over-running. These switches are generally arranged in the armature circuits of the motors, and with their cable connections, have to be of sufficient capacity to deal satisfactorily with the maximum currents possible in practice. Unlike ordinary circuit breakers, they are not designed for interrupting heavy currents, and there is necessarily a considerable amount of wear and tear if they are brought into operation very frequently.

Such switches have not been generally applied to limit the travel of overhead cranes for several reasons; the principal one being that, owing to the large amount of energy stored in a heavy crane when running at a high speed and carrying a heavy load, it is necessary, in order to prevent the crane from running over the end of the gantry, to arrange the limit switch so that current is cut off from the motors while the crane has yet a considerable distance to travel. The ordinary limit switch breaks the motor circuit entirely, and it is, therefore, impossible to cause the crane to continue to travel beyond the point at which the limit switches operate, although the switch is generally arranged so that it is possible to return in the opposite direction. It is, therefore impossible, in such a case to manouvre the crane anywhere near the ends of the gantry, and consequently a large proportion of the area included between the gantries must remain either unserved or very inefficiently served by the crane.

Limit Switches.

These objections may be overcome by special forms of limit switches, such as have been introduced by the British Thomson-Houston Company, which operate by short-circuiting the low volt release device on the circuit breaker of the crane control panel. One form of this switch is designed for limiting the travel only, and is, therefore, suitable for the hoisting and traversing motions, when the latter is made at moderate speed, as is generally the case. In the case of the traveling motion, which is generally made at a much higher speed, it is evidently desirable that within a certain distance of each end of the gantry it shall be possible to travel in either direction at such a reduced speed, that the current may be cut off entirely, and the crane brought quickly to rest when it is quite close to the end of the gantry, so that there is no danger of over-running. This may be effected by the use of a limit switch, so arranged that when the crane is near the point where an ordinary limit switch would open the circuit entirely, the speed is reduced by the insertion of resistance in the traveling motor circuit, which, quite close to the end of the gantry, is opened altogether.

Another possible source of danger is the attainment of very high speeds when heavy loads are being lowered, and devices are now made which render a mishap of this kind impossible. The objection to very high speeds of lowering is that the motor which drives the hoisting motion may be driven at such a speed as seriously to injure, if not break, the fastenings of the armature coils, an injury which might result in the wreckage of that portion of the crane.—The Times.

HEATING REINFORCED CONCRETE BUILDINGS.

AMONG the many advantages of reinforced concrete the heating proposition is not usually emphasized as strongly as it should be. In discussing this subject before the annual convention of the National Association of Cement Users, Leonard C. Wason, of the Aberthaw Construction Co., pointed out, that experience seems to show that with concrete floors, it takes longer to heat up the structure for the first time, than in the case of wood floors. However, after the building has once become thoroughly warmed up, it requires much less heat to maintain a constant, comfortable temperature than does mill construction, so that the heating account in the long run, appears to be considerably cheaper with concrete. Where the heating expense is of considerable magnitude, this feature might very properly be seriously considered in the choice of building material.

Gossip of the Trade

The city of Montreal has awarded the contract for eight concrete mixers to Foss & Hill, Canadian representatives of the London Concrete Machinery Co. The price was $9,628.

The Coventry Chain Co., Coventry, England, inform us that their "Coventry" chains are fitted to the new government airship, "Delta" for propeller tilting purposes, and to the "Beta" for propeller driving.

P. G. Smith, Sec., the J. D. Smith Foundry Supply Co., Cleveland, Ohio, has taken charge of the firm's Eastern offices, at 378 Ellicott Square Bldg., Buffalo, N.Y., from which point all the Eastern and Canadian trade business will be handled.

Mr. Howard, president the Detroit Foundry Supply Co., is making a trip through Canada in the interests of his firm. They manufacture and deal in foundry supplies and equipment, also polishing and plating supplies. A new catalogue covering the latter will be issued shortly.

W. C. Mitchell, for some time general superintendent of the Dominion Steel Company, has accepted the position of superintendent of the Algoma Steel Company, and leaves shortly for Sault Ste. Marie.

The Foss & Hill Machinery Co., Montreal, have been appointed agents in the Province of Quebec, for the Queen City Machine Tool Co., Cincinnati, Ohio, manufacturers of metal shapers, and also for the Hoefer Mfg. Co., Freeport, Illinois, makers of drill presses.

The Vancouver and Prince Rupert Meat Co., New Westminster, B.C., has purchased and are installing a 30-ton, 2 cylinder, double acting, vertical ammonia compressor, made by the Armstrong Machinery Co., Spokane, Washington, for operation at the new abattoir and packing plant on the Frazer River; the same to be operated under a direct expansion system.

The John Inglis Co., Toronto, have received an order for a direct-acting, horizontal compound duplex steam pump from the town of Chapleau. The steam cylinders are 10½ and 18½ inches dia., the water cylinders 12 inches dia., and the stroke of all is 12 inches. The duty required is 1,000 imperial gallons per minute; the pressure being 70 pounds for domestic service, and 130 pounds for fire service.

Another order lately received from the Owen Sound Electric Light Station calls for a horizontal tandem compound Corliss engine with cylinders 16 and 36 inches dia. by 36 inches stroke, developing 300 i.h.p., at 75 r.p.m.

In addition to the above the firm have secured an order from the city of Gananoque for a horizontal cross-compound pumping engine, to deliver 1½ million imperial gallons per 24 hours against a domestic pressure of 60 pounds and a fire pressure of 115 pounds.

INDUSTRIAL AND CONSTRUCTION NEWS

Establishment or Enlargement of Factories, Mills, Power Plants, Etc.; Construction of Railways, Bridges, Etc.; Municipal Undertakings; Mining News.

FOUNDRY AND MACHINE SHOP.

LUNENBURG, N.S.—A local company has been successfully formed in this town to carry on the manufacture of gasoline engines, mill gear of all kinds and do general repair work. A. E. Ernst formerly supt. of the Truro Foundry Co., is in charge.

CORNWALL, ONT.—Jas. E. Quig & Co., Engineers and Machinists, have opened up a machine shop here and will do all kinds of work in the line of engineering, machinery, boiler making and blacksmithing.

OTTAWA, ONT.—A. E. White, of Wisconsin, a prominent manufacturer of saw swodges and sawmill machinery, contemplates establishing a branch here.

DANVILLE, QUE.—John O'Donnell has opened a garage and repair shop here.

TORONTO, ONT.—The Noon Universal Coupler Co., capitalized at $100,000, have been incorporated.

FORT WILLIAM, ONT.—Sir Wm. White has announced that it would be impossible to build a locomotive repair shop any place east of Alberta, as by the time the shops were completed the company expect to have 800 locomotives waiting to be repaired in them. To haul those locomotives to the head of the lakes would be entirely out of the question. He expressed the opinion that the head of the lakes was, however, a suitable place for car building shops.

WEYBURN, SASK.—Messrs. Acton and Montgomery have acquired the Weyburn Machine Shop from A. Huel.

OTTAWA, ONT.—The International Foundry Co., of London, capitalized at $75,000, have been incorporated.

NEW YORK.—The Canadian Pacific has ordered 3,000 tons of rails, which will be rolled by the Lackawanna Steel Co. for quick shipment to Kingston, Canada. Recent export business also includes a contract for 20,000 tons of structural shapes from bridge builders in Canada.

BELLEVILLE, ONT.—The rolling mills have been closed down of late and extensive improvements are being made. The furnaces are being rebuilt and several new machines are being installed.

TORONTO, ONT.—Work on the new dry dock for Toronto at the Polson ship yards is about to commence. It will be of steel with concrete foundation and in three sections. When coupled together it will be 600 feet long, 100 feet wide and admit a vessel 80 feet wide. The Polson Company expect to have two sections of dock completed this fall. The cost will be $900,000.

INGERSOLL, ONT.—The John Morrow Screw Co., who announced recently that they would expend $150,000 on improvements, have awarded a $20,000 contract for building to Nagle and Mills.

VANCOUVER, B.C.—The Pacific Electric Heating Co., of Ontario, Cal., is establishing a plant here for the manufacture of "Hotpoint" electric irons and various other electric appliances. R. R. McCrea is manager.

WINNIPEG, MAN.—The Canadian Northern closed a $300,000 contract with the Canada Foundry Co. recently for a number of freight and passenger locomotives to be delivered this fall.

BLAINE, B.C.—John Nicoll has purchased the personal property of the Blaine Foundry & Machine Company, and is now in charge of the foundry and machine shop located on E street.

TRENTON, ONT.—The factory of the Barr Registers is being put in shape here by W. H. Matthews and Mr. Barr. The Canada Iron Mines, Ltd., will establish a new concentrating plant here also.

WELLAND, ONT.—A new foundry and moulding department has been added to the plant of Quality Beds, Limited. This addition is of brick construction and is of the very latest design, size 60x80. The addition will practically double the output.

MONTREAL, QUE.—The Dominion Bridge Co. is taking steps to enlarge its holdings south of the Grand Trunk Railway tracks at Lachine. It is said that the property between the works and the Rockfield boundary are to be acquired.

WELLAND, ONT.—The new factory of the Imperial Manufacturing Co. is in course of erection. The firm is entirely new and independent, having no connections in the States. Hardware specialties of all kinds will be manufactured.

ESTEVAN, SASK.—Walstead and McGraw, machinists and automobile experts, of Kenmare, N.D., have acquired the Skinner Electric Light building, and intend running an up-to-date auto garage and machine shop.

OTTAWA, ONT.—Letters patent of incorporation have been issued to the Thomas Davidson Manufacturing Co., Montreal, with a capital stock of $5,000,000. The company is authorized to carry on the business of smelting, casting, etc. The incorporation is through Buchan and Dillon, advocates.

WOODSTOCK, N.B.—Small and Fisher's machine shop was badly damaged by fire recently. The moulding shop was gutted.

GUELPH, ONT.—Guelph has secured another industry, the Canadian branch of the Flexible Conduit Co., of Penn Yan., N.Y., which manufactures electrical conduits.

OTTAWA, ONT.—In connection with the option secured upon extensive property on the Richmond road, it is learned on reliable authority that it is intended mainly for ma-

A.L.A.M. Standard

Castellated and Plain Nuts Milled from the Bar

are carried in stock at factories and warehouses. The essential features of a good Nut as found in our product are:—

EDGES—Smooth and well defined.
HOLE—Central and true.
CUTOFF—Clean and without burrs.
TAPPING—Straight and accurate.

Nuts varying from standard furnished quickly and reasonably.

chine shops and other appurtenances to the Canadian Northern Railway.

REGINA, SASK.—The Cockshutt Plow Co. will erect a $50,000 warehouse in this city.

VANCOUVER, B.C.—The largest mechanical pulp mill in Canada will be situated at Ocean Falls. The Ocean Falls Co., Ltd., head office this city, have secured all the machinery possible from local sources, and are erecting a fully equipped plant that will eventually employ 700 men.

EDMONTON, ALTA.—The Edmonton Ironworks Co. are erecting a foundry and warehouse at a cost of $10,000 each and will engage in the manufacture of plows.

PRESTON, ONT.—The Preston Woodworking Machinery Co. have received a charter and are preparing to erect a factory 100x100 ft. and a moulding shop 40x60 ft.

ST. JOHNS, P.Q.—W. J. Walsh, head of the Holyoke Steam Boiler Works, contemplates establishing a plant here. The Holyoke Steam Boiler Works are by no means a new venture and have already filled large contracts in Canada and in Newfoundland, besides having many big orders ahead.

ST. CATHARINES, ONT.—Machinery has been installed in the Welland Vale factory, to be used in the manufacture of rakes. The rakes will be welded by electricity.

THOROLD, ONT.—The Coniagas Reduction Co. suffered a $15,000 loss by fire recently. The fire nearly wiped out the blast furnace.

BROCKVILLE, ONT.—Local capitalists have formed what will be known as the Atlas Motor Car Co., for the manufacture of automobiles. The company, which is capitalized at $200,000, has started work on the erection of a factory.

MEDICINE HAT, ALTA.—The Alberta Foundry and Machine Shop have commenced operations. Castings of iron and brass will be turned out for general building and corporation work as well as machine parts, pipe connections, etc. The pig iron used is obtained from Port Arthur, the scrap iron locally.

MEDICINE HAT, ALTA.—The installation of the machinery at the Alberta Rolling Mills is nearing completion. The boilers and one engine are installed and the machine shop department is already running, turning the big rollers to the proper size for the mills. The management expect to commence rolling by August 10th.

A Small Item

APPARENTLY, but how many hours a week are your men regrinding and rehardening tools?

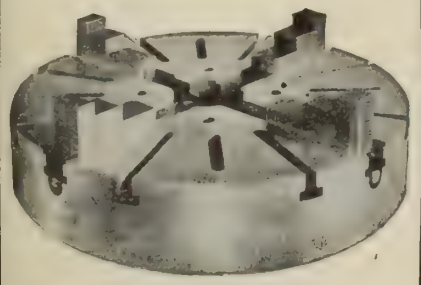
You can cut this time to a fraction with our latest model.

Plenty of water, the right kind of wheel, rigidity and no lack of belt power put your grinding on a "delivering the goods" basis.

The men appreciate a machine that expeditiously puts their tools in the best condition.

THIS SPELLS "OUTPUT"

Built in Two Sizes—16 inch and 20 inch Wheels
Net Weight of Machines, 650 lbs and 875 lbs.



THE FORD-SMITH MACHINE COMPANY
HAMILTON, ONTARIO

From 1/8 to 3/4 of a pound of our 99% pure
ALUMINIUM GRANULES
to the ton of steel or iron will increase the tensile strength of your castings without decreasing the ductility—it will produce smooth faced castings and avoid blow holes—therefore will reduce your loss in castings to a minimum.

MALLEABLE IRON CASTINGS
PRATT & LETCHWORTH CO.
BRANTFORD ONTARIO

FORT WILLIAM, ONT.—The Steel Company, of Canada, has taken over the Fort William proposition of the Superior Rolling Mills Company, and are preparing to establish a plant here.

SAULT STE. MARIE, ONT. The $4,000,000 mill of the Lake Superior Pulp and Paper Co., will be located on this side. The new building will be 500 by 180 feet and will take eighteen months to erect. A new cofferdam is being constructed to augment the power now supplied to the pulp mill, and the output of pulp will also be increased by another 500 tons per day to supply the paper plant. A battery of fourteen boilers is also to be installed in the old power house of the sulphite mill. The plant will employ about 300 hands. Bonds to the value of about $3,500,000 were floated in London several weeks ago. The industry, when completed, will represent an investment of $8,000,000.

VANCOUVER, B.C.—Capitalized at $10,000,000, the British Columbia Steel Corporation has announced that immediately at Port Mann construction will be undertaken of the first unit of the great steel plant. Plans have been decided upon for unit No. 1, which will cost $700,000.

TORONTO, ONT.—The Canada Foundry Co. have delivered 1,500 feet of the order of 3,500 feet of new intake pipe given them by the city council at their meeting of May 29. According to the contract between the city and the company, the whole order of 3,500 feet is to be delivered in 90 days, the manufacturers getting a bonus of about $11,000 for getting the work done with extra despatch.

WELLAND, ONT.—Contracts for the erection of four additional buildings to the plant of the Page-Hersey tube works were let last week to David Dick & Sons. The total cost of these buildings will be about $40,000. The new buildings will consist of pumphouse, pattern shop, storehouse building and butt weld mill. Each building will be constructed of brick and steel.

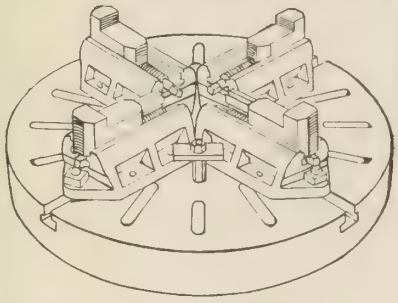
NORTH VANCOUVER, B.C.—The Wallace shipyards were wiped out by fire recently.

ORILLIA, ONT.—The National Hardware Co., which manufactures door locks, etc., is erecting a $16,000 addition. The Canada Refining and Smelting Co. is doubling its capacity.

In Thousands of Machine Shops

Shelby Seamless Steel Tubing

is saving time, reducing costs and improving products. Because it is made in hundreds of sizes and gauges and almost any section---because it can be bent, coiled, flanged, expanded, swaged or upset---because it is remarkably homogeneous and strong---it offers short cuts in hundreds of manufacturing operations.



There is almost a certainty that **YOU** could use Shelby Steel Tubing to advantage. Write us for booklet, suggestions, stock list and prices.

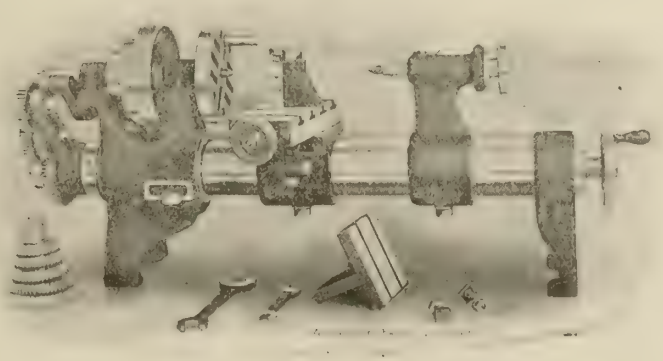
The Cushman Chuck Co.

Hartford, Conn., U.S.A.

Established 1862

THE MANAGER OF

THE LARGEST WORKS IN CANADA



must at times feel the need of an inexpensive lathe for his private experimental work. Much good thought and invention die out for want of easily and cheaply making experiments or models of an idea, a whole workshop of expensive tools usually being required, although the model needed may be small.

WE HAVE DESIGNED A TOOL FOR THIS WORK

A complete, self-acting, sliding, boring and screw-cutting lathe, 4 in. centres, 2 ft. 4 in. bed, capable of doing all plain milling, keyway cutting, etc.

ITS COST IS $24 AT WORKS IN ENGLAND

There is no suggestion of toy about it; it is a tool rigid enough for the heaviest work it can hold.

EGANVILLE, ONT.—During the recent fire here the machine shop and harness shop of M. J. McCann were destroyed. Loss $6,000.

HAMILTON, ONT.—The Marsh Standard Cable Co., Pittsburg, has decided upon Hamilton, Ont., as the point at which to establish its Canadian plant, to cost $500,000. A site has been chosen. Other United States companies that have arranged to establish branch works in Hamilton are the Boston Insulated Wire & Cable Co., Dorchester, Mass.; Taylor Mfg. Co., Princeton, Ind., makers of store fittings, etc., and Mayor Brown Co., manufacturers of brass and stencil goods.

TORONTO, ONT.—James H. Havill, architect, Toronto, has prepared plans covering a fireproof factory building for the C. A. Dunham Co. on the corner of Primrose Avenue and Davenport Road, Toronto, and tenders have been called for it. The C. A. Dunham Co., Ltd., are the manufacturers of the Dunham vacuum steam heating system used in many of the principal buildings in Canada. The head office of the company is 511 to 513 Continental Life Building, Toronto, with branch offices in Winnipeg, Vancouver and Montreal.

MUNICIPAL.

CALGARY, ALTA.—The by-law endorsing an expenditure of $20,000 for sewer purposes, was carried.

WINDSOR, ONT.—The waterworks by-law for $50,000 was carried.

WILKIE, SASK. The by-law to raise $25,000 for waterworks was carried.

NANAIMO, B.C.—The burgesses passed the $50,000 sewerage extension by-law.

TORONTO, ONT.—Final assent was given by council to the issue of $745,173 general consolidated loan debentures for repairs to the waterworks intake pipe and for a new intake and six foot steel conduit and additional water mains for the water system of the city.

SASKATOON, SASK.—Big municipal improvements are planned for Saskatoon. The plans are for a $25,000 waterworks system and other improvements.

CORNWALL, ONT.—The ratepayers passed a by-law to raise $30,000 to lay an additional water main from the pump house to the centre of the town and thence east, north and south by 12-inch mains.

WINGHAM, ONT.—The voters carried the $5,000 by-law for the completion of a pure water system.

RAYMOND, ALTA.—The town council passed a by-law authorizing the raising of a loan of $10,000 for waterworks.

DRESDEN, ONT.—The council have instructed E. W. Farncomb, C.E., to prepare the necessary plans and specifications for the proposed waterworks and to proceed with the installation of the system as soon as possible.

ST. LAMBERT, QUE. The town authorities will take up the study of plans for the purpose of establishing a plant equipped to prepare all its sewage flowing into the river as early as possible. Engineer Dickinson has already studied the question and has presented plans for a thoroughly up-to-date sedimentation plant with filtration beds.

CARLSTON, ALTA. The ratepayers have voted $40,000 for a gravity water system.

ELECTRICAL.

EGANVILLE, ONT.—The electric light plant, sawmill and block owned by J. D. McRae was destroyed in the big fire here recently. Loss $10,000; insurance $2,500.

KAMLOOPS, B.C. Kamloops is getting ready to expend $200,000 in developing 5000 horsepower on the Barrier River, a tributary of the North Thompson River. The power will be conveyed forty miles to Kamloops, where it will be utilized in pumping water for the reservoir and waterworks system as well as for industrial purposes.

NAPANEE, ONT.—The by-law authorizing the town to sell the municipal electric plant to the Seymour Power Co. was carried. The town sells the plant to the Seymour Co. for about $40,000, and gives the company a thirty-year contract, and secures electric light at eight cents net a kilowatt hour for consumers.

ORILLIA, ONT.—A by-law to raise $80,000 for enlarging the town's power and light plant was carried.

INGERSOLL, ONT.—The council passed a by-law for the raising of debentures amounting to $25,000 for extensions and alterations to the electric light plant.

TORONTO, ONT.—The General Hospital Board have decided to instal a private plant for generating electric power of the capacity of 400 kilowatts.

HAMILTON, ONT.—The by-law providing $305,100 for a municipal power plant was carried.

WILKIE, SASK.—The ratepayers passed a by-law authorizing an expenditure of $10,000 for an electric light system.

NEW BOILER SHOP.

The Polson Ironworks Co. will build, adjoining the new dry dock to be constructed by them at the foot of Frederick street, Toronto, a boiler shop, composed entirely of steel, excepting one wall of brick. The dimensions will be 300x120 feet. Two flange compartments will be erected; one 60x40, will be used as a pump and compressor room, the other, measuring 60x60, to be used as a flange fire shop, the construction being such that fumes, etc., will not reach the main boiler-making section. The roof of the boiler shop will be fireproof asbestos.

PARTNERSHIP DISSOLVED.

The partnership of the well-known firm of engineers, Ross & Holgate, has been dissolved. Henceforth the business will be continued under the name of R. A. Ross & Company.

Henry Holgate, who has been associated with Robert A. Ross for the past ten years, has joined the Cedar Rapids Power Company, and will take over the control of that concern as president. Ross & Holgate, during their partnership, were concerned with the establishment of some of the best known electrical works in the country, notably the Hydro-Electric and the West Kootenay Companies. They were also consulting engineers for the Canadian Pacific Railway, and it was under their supervision that the Angus shops were laid out. Mr. Holgate was chairman of the commission which was appointed to investigate the cause of the collapse of the Quebec bridge.

DRUMMOND BROS., LATHES.

Drummond Bros., Ltd., Ryde's Hill, Guildford, Surrey, Eng., are introducing their various lines of manufacture on the Canadian market, and as steps are being taken to secure suitable representation throughout the Dominion, a brief account of the different specialities offered is as follows:

The New Model-Maker's "Precision" Lathe is designed to meet the wants of model makers, who require a tool capable of very varied and accurate work, combined with a sufficiently low price to enable satisfactory pursuit of this fascinating and useful hobby.

The 3½-inch Centre Back-Geared, Self-acting, Sliding, Boring and Screw Cutting Lathe has been designed specially for Model Engineering and Precision Work, inventor's model work or light running repairs to motors and has in this respect many attractive and useful features.

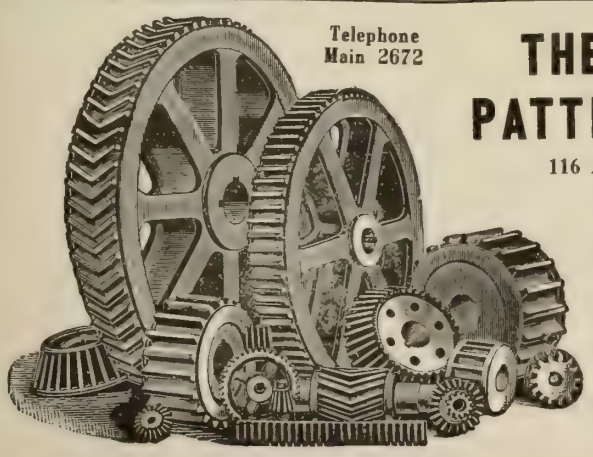
The new design "Workman's" lathe meets the wants of motor and cycle repairers, general machinists, etc., and provides a reliable tool at moderate cost to those of limited capital.

The 9 and 7½-inch SSS lathe is designed for the use of high-speed tool steels, up to the full capacity of modern steel production.

The 5-inch SSS lathe for treadle or power is adapted for repairs to motors and motor cars, and is claimed to be the only lathe of its size, built with the special idea of overtaking this class of work.

In a future issue, fuller illustrated detail descriptions will be given of these machines.

ANOTHER BIG MERGER.



A merger has been effected of several well-known industries of Canada. Those interested are the Perrin Plow & Stove Co., of Smith's Falls; the Tudhope-Knox Co., of Orillia, makers of steel truck; the Tudhope-Anderson Co., of Winnipeg, and the West Lorne Wagon Co.

The new concern will be known as Tudhope Co., Limited, and it will be capitalized in the millions. The headquarters will be at Orillia, and F. J. Oliver, who is the chief shareholder

of the Perrin Plow & Stove Co., will be manager. A large addition will be made to the Tudhope-Knox Co. plant at Orillia, and work has already been begun on it. The plow plant of the Perrin Co. will be transferred from Smith's Falls to Orillia, but the stove plant will remain there and will be greatly enlarged.

PLOW CONCERNS UNITE.

The announcement has been made that the Cockshutt Plow Co., of Brantford, and the Frost & Wood Co., of Smith's Falls, have united their sales departments by a mutual understanding. Under this arrangement, the Cockshutt Co. will take charge of all territory west of Peterboro, acting as sole agents for the Frost & Wood Co., and the reverse will be true east of Peterboro in Ontario, Quebec and the Maritime Provinces. It is claimed this will build up a stronger sales department at a minimum of expense, and that it will secure the best local agents for the two companies. In addition to the manufacturing plants at Brantford and Smith's Falls, which are about to be considerably enlarged, these companies have large distributing offices at Ottawa, Montreal, Quebec, St. John, Truro, Charlottetown, London, Winnipeg, Brandon, Regina, Saskatoon, Edmonton, Calgary, New Westminster and Victoria.

CANADIAN TUNGSTEN LAMP CO.

The annual meeting of the Canadian Tungsten Lamp Co., Ltd., was held at the head office of the company, Hamilton, on Wednesday, July 5th. All the shareholders, with two exceptions, being present.

Mr. Ginder, the president and general manager, presented his annual statement, showing a business increase of nearly 40 per cent. over the previous year, and, notwithstanding the immense amount of money spent in research work in their laboratory, the balance to the credit of the profit and loss account was deemed most satisfactory. The usual dividend was declared. The directors retiring were unanimously re-elected, viz., W. H. Ginder, president and general manager; F. W. Gates, vice-president; P. D. Crerar, K.C., honorary treasurer; Geo. Webb, A. Ward and G. H. Levy, board of directors.

An executive committee of three was elected, before whom all vital questions will be brought and decided upon, this committee reporting full particulars to the board of directors at their monthly meeting.

The company own a large piece of ground in the rear of their factory, and the question of building a five-storey extension was fully discussed. The president was instructed to get plans and specifications so that arrangements could be made to commence immediately this most necessary addition.

CONTRACTS OPEN.

WILKIE, SASK.—Sealed tenders will be received by T. A. Dinsley, secy.-treas. of the Town of Wilkie, until noon, Monday, August 21st, 1911, for supply and delivery of the following machinery, materials, etc.:

Tender A: electrical machinery—

(1) One 60 k.w. 3-phase, 60-cycle, 2,200 volt a.c. generator.
(2) One exciter for above.
(3) One marble switchboard, instruments and switches.
(4) Three 2,200 volt motors, back-geared to pumps.
(5) Five Transformers for lighting system.
(6) Series Tungsten Street lighting system.
(7) Approximately 25 cwt. of weatherproof copper wire (line material, guy wire, arms, pins, insulators, etc.).
(8) Cedar poles.

Tender B: one 100 I. H.P. International Combination Engine.

Tender C: Pumping Machinery—

(1) One working head and deep well cylinder.
(2) One half-million gallon pump.
(3) One air compressor.
(4) Necessary shaftings and belting.

Tender D: one Pneumatic Storage Tank.

Tender E: approximately 1,100 ft. 8-in. cast-iron water pipe.

Approximately 4,800 ft. 6-in. cast-iron water pipe.

Approximately 2,000 ft. 4-in. cast-iron water pipe. 15 hydrants and 22 valves.

Tender F: Trenching, laying cast-iron water pipes, hydrants, valves, etc., and back filling.

Plans and specifications may be seen at the office of the Secretary-Treasurer of the Town of Wilkie, or on application to the Engineers, McArthur & Murphy, Room 8, Bottomly Block, Saskatoon, Sask.

LONDON, ONT.—Tenders are asked for about 3,300 feet of 18-inch, and 1,600 feet of 12-inch cast-iron pipe, with a number of valves and specials. Tenders received not later than noon August 12th, 1911. For specifications and forms of tender, write H. J. Glanbitz, General Superintendent, Waterworks and Electrical Depts., London, Ont.

VIRDEN, MAN.—Tenders will be received until August 18th, 1911, for the installation of a steam heating plant in the Virden Municipal Hall. Plans of building may be seen and other particulars obtained at the office of J. F. C. Menlove, Town Clerk, Virden.

CATALOGUES.

The Armstrong Bros.' Tool Co., Chicago, have sent us Booklet No. 4, descriptive of their Ratchet Drills. Four different types: the Packer, Standard, Universal and Short, each covering a particular service requirement, are offered by the firm to meet any kind or condition of work.

Simonds Canada Saw Co., Montreal, Quebec, St. John and Vancouver, have forwarded us several of their "Cigar Fan Novelties," their "Guide for Millmen" and "Wall Poster Leaflets." The cigar fan, when extended, gives a faithful representative of a saw, and suggests the continued ingenuity of the firm in bringing their manufactures prominently before users. The Guide to Millmen, in addition to useful information on saw questions, contains much good advice concerning health and habits. The Wall Poster is devoted to the Simonds "Hack Saw Blades," and should have a prominent place allotted to it where such commodities are in operation.

The Norton Co., Worcester, Mass., have recently issued a book, entitled "Safety as Applied to Grinding Wheels." Illustrated descriptions are given of modern safety devices which can be practically applied to the use of grinding wheels and machines, and in view of the wide attention being directed to this subject, those interested are invited to procure a copy from the Norton Co., Publicity Dept.

The Armstrong Bros. Tool Co., Chicago, have issued their booklet No. 5, containing an ingenious assortment of lathe dogs and clamps. Some of the devices are especially adapted for use on finished work, and can be quickly applied without removing work from centres. A bolt driver of special merit, suitable for square, flat or hexagon, is described and illustrated, and as a time-saver is sure to meet with approval. There are ten illustrations in the booklet and all are of interest to machine shop men. Copies of the publication may be had on application to the Company.

The Mesta Machine Co., Pittsburg, has issued a catalogue devoted to steam-hydraulic forging and bending presses of the Hamel & Lueg type. In these presses, the steam and hydraulic cylinders are direct-connected, thus making it unnecessary to force the water in the press cylinder through pipes, while the machine is in motion. With this self-contained feature, the presses may be economically installed and operated. The catalogue contains several good illustrations of these presses. The Mesta Machine Co. has obtained the exclusive manufacturing rights in the United States and Canada.

The Springfield Machine Tool Co, Springfield, Ohio., have issued a thoroughly well-illustrated Catalogue G., descriptive of the various high-grade lathes and shapers manufactured by them. Each type of machine has its various details clearly shown, enabling those in search of a trustworthy tool, to see at a glance the features set forth. Two types of engine lathe are made, and on each type, five different styles of head may be supplied if necessary. One type represents complete mechanism and design for rapid change of feed and screw cutting, while the other is equipped with a rapid gear feed drive only. The latter permits of a more economical tool in the matter of first cost to the user, and is adapted more as a manufacturing lathe than for tool use. Four different sizes of motor-driven engine lathes are described, as are also the Fox Monitor Turret and Shafting lathes. Crank and back-geared shapers, motor-driven and otherwise, complete with illustrations of bench-straightening presses with centres, and pneumatic presses, the 64 pages of this attractive publication.

BIG FIRMS UNITE.

An amalgamation has taken place between the Canadian Fairbanks Co., Ltd., with head offices in Montreal and numerous branches throughout Canada, and the Fairbanks-Morse Canadian Manufacturing Co., Ltd., with head offices in Toronto, and its subsidiary companies, the Dominion Safe & Vault Co., of Farnham, Que., and the E. & T. Fairbanks Co., of Sherbrooke.

The president of the new concern will be H. S. Fuller, of Montreal, president of the Canadian Fairbanks Co., and the vice-president, P. C. Brooks, of Toronto, president of the Fairbanks-Morse concern.

The capitalization of the new company is to be $2,600,000.

TORONTO, ONT.

WOODSTOCK CO. TO BE WOUND UP.

The Maxmillian Machine Co., which started here some months ago to manufacture pneumatic hammers, has decided to wind up. No single-handed hammer has been successfully made and sold, and trouble has been experienced between the directors and the patentees all the time. It is said that the hammer shown to the Industrial Committee at work, was not the hammer for which the promoters had the patent, so the Woodstock people were stung. The city gave the company $1,250 to start, and this would seem to be lost, unless the settlement is more satisfactory than expected.

OTTAWA—The G.T.R. will erect new coal chutes at Ottawa. They will be of steel, with a bunker capacity of 350 tons, and will do away with the present trestle work, the whole plant being concentrated in a much smaller area. The coal will be dumped from the cars to a pit below the track from which it will be hoisted by electric power to the bunkers which are covered in. It will be a very up-to-date coaling plant, causing no dust and occupying little space. Its site will be just east of the company's carshops and its cost is expected to be about $15,000.

OSHAWA—Oshawa is within a month and a half from Trent water electric power. The transmission line poles are already strung from the Trent river power house at Trenton, 65 miles away from Oshawa, excepting short breaks between Cobourg and Port Hope and between Newtonville and Newcastle. The wires, themselves, will be strung the entire distance to Oshawa on or before Aug. 1, as a second construction gang has recently been put on this work.

NORTH BAY—North Bay will spend $100,000 for new waterworks machinery.

HENSALL—Hensall will install a new waterworks pumping plant.

BOOK REVIEWS.

"Magnetic Properties of Heusler Alloys," by Edward B. Stephenson, has just been issued as Bulletin No. 47 of the Engineering Experiment Station of the University of Illinois. This bulletin is a contribution of data on the subject of magnetic alloys, and describes fully the methods of magnetic testing, thermal analysis and photo-micrography used in the work. The results show that an alloy of ferro-magnetic properties comparable with those of cast iron can be made of the non-magnetic components copper, manganese and aluminum, and that the magnetic properties depend largely on the heat treatment.

Copies of this bulletin may be obtained gratis upon application to W. F. M. Goss, Director of the Engineering Experiment Station, University of Illinois, Urbana, Illinois.

The use of a block of wood on the top of molten brass in a crucible, when pouring is taking place, serves to protect the metal from oxidation and partially prevents the ingress of dross into the mold. The block burns and gives a reducing atmosphere. This practice has been found to give excellent results and is used in some of the brass rolling mills. The block, which should be of wood, which will not snap when burning, is thrown on the surface of the metal after skimming and just before pouring.

Cutting Crucible Costs

Cost and price are distinct terms.

DIXON'S CRUCIBLES

are less costly because of the service you get out of them. They give more heats and more general satisfaction than you usually get from crucibles.

The **Moreau Pulpwood Barker**

The cheapest and most economical barking device on the market to-day.

WASTE: 16 to 18% according to size of wood.
POWER: 6 to 8 horse-power.
CAPACITY: Up to three cords per hour.

We have free demonstration of this barker at Montreal.

Call or write. 485 St. James Street.

Canada Ford Co.

Bakelite

VALVE DISCS

"The Discs That Last"

BAKELITE is the only material yet invented that can be used universally for cold water, wet or dry steam, superheated steam or chemicals.

It has wonderful strength and hardness, and if worn by friction can be reground and refaced.

A percentage of graphite used in their composition gives a lubricating surface, saving the valve seat.

Try BAKELITE Discs under the most severe conditions in your plant, and even with the claims made here for them you will be surprised at the results. BAKELITE can be injured by nothing except careless handling and friction wear.

It is no longer necessary, therefore, to use high-priced special metal discs—BAKELITE Discs keep valves tight no matter how great the pressure or how high the temperature.

Ask your dealer for Bakelite Discs, or write us.

Double Seated Noiseless Back Pressure Valve

The construction of the inner Valve and seats is of such a nature that uneven expansion of the metals will not cause the Valve to STICK or BIND—A FEATURE which places this Valve in a class by itself. ANOTHER FEATURE of our Back Pressure Valve is that it can be placed in ANY POSITION.

It is a DISTINCT improvement on the OLD STYLE single seated Valve. It has a DOUBLE PISTON TYPE of inner Valves, with disc of different area.

Guaranteed close regulation without excessive weighting. Carried in stock from 2 to 16 inches.

THE SOURCE OF REAL SERVICE

in tools springs from the use of a grinder which keeps them always in perfect condition. A very economical and efficient one is

BLOUNT'S

WET TOOL GRINDER

which can be run continuously if desired. It is fitted with self-oiling bearings, and there is no wear of parts, because the propeller of the pump, furnishing a constant supply of water, is loosely fitted, and does not touch the case at the nearest point. A sleeve cap prevents leakage without the use of packing.

BROWNING CRANES

SAVE MONEY

Time and Trouble by installing the Browning Locomotive Cranes.

They are built to handle easily the heaviest lifting in contracting, logging enterprises, etc., and never fail to deliver the goods under any condition.

Users of Browning Cranes have found them to be worth many times their cost. Why not investigate this economiser? You will never regret it.

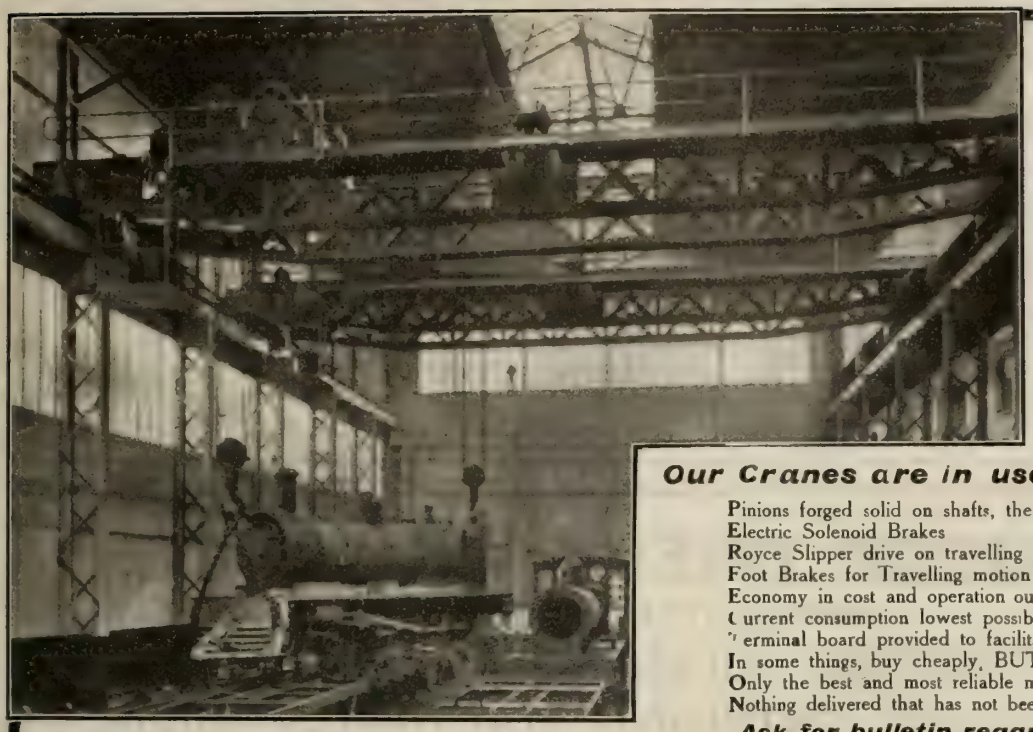
The Browning Engineering Co.
CLEVELAND - - OHIO

Cyclone Hoists

are simple and efficient. All bearings are graphite bronze, self lubricating, and require no oil.

They have 80 per cent. efficiency and are of ½ to 20 tons capacity. We stock from ½ to 5 tons, but can supply greater capacity at short notice.

Matchless Trolleys



will pick up and move any load and place it just where you want it. They are adjustable to any size "I" beams.

We also carry Gravity Molding Machines, Jar and Squeeze Molding Machines, Hauck Oil Burners, Acme Parting, Red Facing.

A post card will bring you our catalogue.
Send for it to-day.

The Making of Hollow Castings

The recent introduction of King Kore Kompound has now rendered this, once somewhat difficult, part of Foundry practice comparatively easy.

It has, also, reduced the core expense by more than one-half.

This compound is a black, dry powder, and is used as flour is used, but with one-half the quantity is produced greater and better results.

Its use avoids the danger of swelling or "blowing." The core easily comes out of the casting, and when old cores are ground up, in the rattler, or otherwise, the sand so made is used over again.

The core compound it contains, again becomes a binder under heat of the core oven, as it melts, and so it is used over and over again.

This is Foundry Economy; Flour, Rosin, etc., are now luxuries.

A barrel of King Kore Kompound will be sent "subject to approval" to any inquiring mind.

That is the **Stevens' System** of trying before buying.

I have copies of proportions of compound to sand used and methods followed in core rooms of Foundries in thirteen different States. This information, with other printed matter relative to the subject, will be mailed on request.

I maintain a direct branch at 137 Jarvis St., Mr. J. M. Mayers, Manager, Toronto, Ont., where is stocked a supply of **Foundry Facings, Foundry Supplies, Buffing Compositions**, of my own manufacture.

The stamp of quality pervades them all.

FREDERIC B. STEVENS

Main Office - - - - - - DETROIT, MICH.

Canadian Branch - - - 137 Jarvis Street, TORONTO.

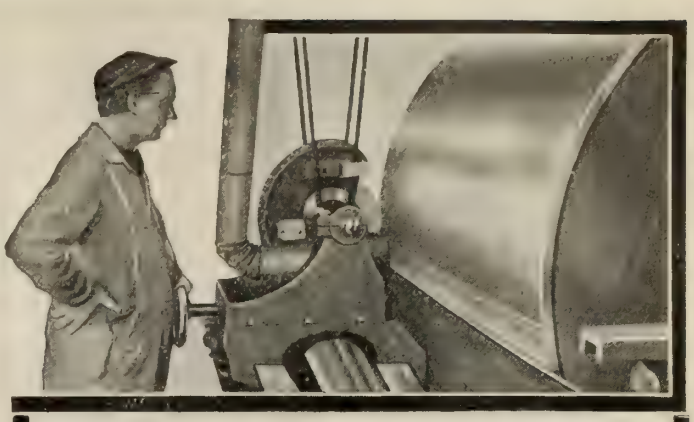
FREE INSTRUCTION BOOK



This book should be within instant reach of every engineer. It tells clearly, by photograph and formula, how to use the well-known Smooth-On Iron Cements in repairing boilers, engines, castings, tanks, joints, etc.

Used according to instructions, Smooth-On Cements will save more actual time and money in the engine and boiler room than any single product manufactured. Their uses are innumerable, and their repairs absolutely permanent.

Smooth-On Mfg. Co.,

JERSEY CITY, N.J.

For Sale by Supply Houses.

Saving a Week In 2½ Hours

IT TAKES a Carborundum Wheel just 2½ hours to grind a cast iron drum 60 inches in diameter and 60 inches wide. Seven full 10-hour working days is the shortest time in which the best of other wheels ever did the same work under precisely the same conditions.

As the man on the job said, "Life is too short to experiment with other wheels."

The drums are ground at the plant of the foremost manufacturer of wool and worsted machinery. The drums are first turned down and 1-32 is left for grinding. A 14-inch Carborundum Wheel is used and it grinds as many drums in a day as other wheels would grind in a month, cuts clean and gives a better finish.

Carborundum Grinding Wheels

are the wheels of to-day and to-morrow. You should realize from the records made in other shops just how much they will increase and better the work in your shop. Let us tell you how to get the right wheel in the right place.

A GOLD MINE

SAVE YOUR IRON

SLY'S PATENT IRON CINDER MILL
Patented, No. 514097. Patented, No. 841728.

may be at your disposal on your very premises. Look out of your side window or back door and see if you have not an accumulation of cupola dump, and other foundry refuse, which is a total loss to you in its present state. Why not add to your profits and install one of the Sly Patent Cinder Mills to reclaim this iron and be astonished at your former loss and pocket the rich re. turns from your newly-discovered mine-

Sly's Patent Iron Cinder Mill will save 95% of the iron contained in your cupola dump and gangway scrapings and 75% of the coke. Iron is valuable, then why throw it in the dump? Iron recovered by this Mill is better than machinery scrap. Study economy in a foundry and your profits will increase accordingly. Mill will pay for itself three or four times every year, and we have records of Mill paying for itself twelve times a year. Let us know amount of your daily melt and we will quote. *Write for Cinder Mill Catalogue F.*

We also manufacture Cleaning Mills, Dust Arresters, Sand Blast and Foundry Equipment.

"MORSE"

Twist Drills

will do your work as you want it done.

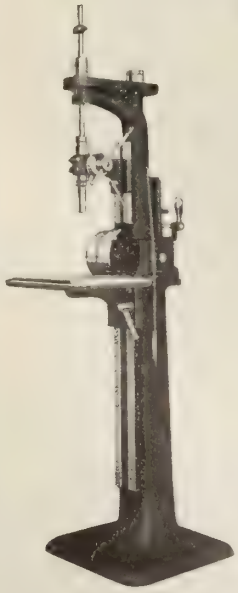
MORSE TWIST DRILL & MACHINE CO., New Bedford, Mass., U.S.A.

Our goods are handled by---Rice Lewis & Son, Ltd., Toronto; Aikenhead Hardware Co., Ltd., Toronto; Frothingham & Workman, Montreal; Mechanics Supply Co., Quebec.

Three Minutes' Grinding puts a new and stronger tang on the shank. It fits the lower slot in the socket.

What Do Your Twisted-Off Tangs Cost?

Keep account for a time of the new drills used to replace those thrown into the scrap heap because of twisted-off tangs, and you will see. These scrapped drills are all right in every other respect.



The "PERFECT" Double-Tang Socket

gives a simple, effective, and inexpensive means of eliminating this cost and putting the drills back in money-earning shape. **Write for Folder A.**

WHY HESITATE?

Settle that Twist Drill Proposition now.

Your factory cost sheets tell the story of excessive manufacturing expense, lost production and imperfect products.

It is not necessary for you to experiment. We have done that for you and can answer any shop question regarding Drills, if you will confer with us or our jobbers.

We have conducted comparative tests in our testing department, to solve all drilling problems. These results are at your command and we will tell you where "W & B" Diamond Drills will settle that question of factory costs, and increase your output

"W & B" Diamond Trade Mark

is a guarantee of the highest efficiency in drills. It means that they are constructed of the RIGHT MATERIALS and WORKMANSHIP, backed by SCIENTIFIC and MECHANICAL Study. Combining these with experience has enabled us to produce the most efficient line of Twist Drills in use to-day.

TOOLS OF QUALITY BEAR THESE MARKS W&B

Ask your jobber for "W & B" Diamond Drills or write us. Catalogue No. 74C.

Canadian National Exhibition

Toronto

August 26th to Sept. 11th, 1911

Greatest Exhibits of Manufactures, Machinery, etc., on the Continent.

Coronation Year Attractions.

Festival of Empire. Band of Coldstream Guards.

Coronation Year Fireworks.

FOR INFORMATION WRITE

Geo. H. Gooderham, M.P.P., PRESIDENT.

J. O. Orr, SECRETARY.

The Technical Papers of To-day

ARE THE

Textbooks of To-morrow

¶ **Therefore,** Be in advance of the times by binding your copies of Canadian Machinery. To help you do this and, in addition, assist you in keeping them clean and easy of access for reference, we will send Canadian Machinery for one year and a "Common Tie" Binder for $1.50, or to present subscribers we will furnish the binder at 50c. each post paid.

¶ At the end of the year a complete alphabetical index will be furnished free.

"BARR" Combined Drilling and Tapping Machine

A COMBINATION THAT WILL SAVE YOU MONEY

The "Barr" Combined Drilling and Tapping Machine will do the work better than two separate machines and save both space and labor.

We can give you power feed, lever feed and tappers in any combination from two to seven spindles to a machine.

Write for prices and details.

ASK OUR AGENTS TO MAKE A DEMONSTRATION OF WHAT OUR MACHINES WILL DO.

OTTAWA TORONTO WINNIPEG

B. & S. Cutter Grinding Machines

No. 2 Cutter Grinding Machine.

Our line of cutter grinding machines is extensive and embraces machines to handle all styles and varieties of cutters.

NO. 2 CUTTER GRINDING MACHINE.

This machine takes cutters to 6 in. diameter and 6 in. length. Thin milling cutters or saws to 24 in. diameter can be accommodated.

NO. 3 UNIVERSAL CUTTER AND REAMER GRINDING MACHINE.

This machine differs from the No. 2 mainly in that a greater variety of cutters and reamers can be accommodated.

NO. 13 UNIVERSAL AND TOOL GRINDING MACHINE.

Can be used not only for grinding cutters of all kinds, but on a large variety of other work.

NO. 23 GEAR CUTTER GRINDING MACHINE.

Takes gear cutters to 8 in. diameter, 2¼ in. thick and 1½ in. diametral pitch.

Send for circular and full description.

This New Gap Lathe Has Solved Many Troubles For Others. It Will Do The Same For You. Speed, Accuracy And Reliability Are Its Strong Points.

DESCRIPTION

Headstock construction prevents chattering, and deep oil chambers fitted with ring oilers make spindles and bearings self-oiling and always well lubricated.

Tailstock of a special type, and sleeve is clamped by a quick acting locking device. Tailstock is secured to bed by bolts adjusted from the top where they are easily accessible.

Bed, non-springing and webbed, and braced to secure rigidity.

Gap, vibration absolutely prevented by use of brace supports to carriage.

Spindle, high carbon hammered steel in solid chilled cast iron bearings, accurately fitted and self oiling.

Carriage and Apron, non-springing under severest strain, full "V" bearings and flat bearings in addition on front ways.

Double Back Gears give eighteen distinct spindle speeds, suiting lathe to work on widely different diameters.

Compound Rest, with graduated base, accurately fitted taper gibs, end adjusted. Screws in both rest and cross slide read to thousandths.

Friction, Safety Feeds, screw and rod feeds cannot be both engaged at the same time. Quick changes of 1¼, 2½ and 5 times thread being cut.

Gears and Racks, cut from solid and steel where necessary.

Screw Cutting, full range of commercial threads provided for.

Equipment, Compound rest, steady rest, follow rest, large and small face plates, wrenches, two-speed, friction countershaft furnished with each lathe.

Accuracy, Strength, Solidity, Wear. These are the paramount features behind all McDougall Machines. Made **to meet extreme demands.**

Canadian Fairbanks Company, Sales Agents **Cable Address: Dougalt, A.B.C. 5th edition**

WEIGHT OR POWER?

When Buying Milling Machines it is better to make horse-power the determining factor rather than mere weight which may be of the "dead" variety.

Weight in the right place, when accompanied by sufficient power, is undoubtedly desirable in all machine tools for heavy work, but weight without power is useless, and suggests possibilities of output that cannot be obtained in practice.

Twelves Inches a Minute

Material Milled	-	Hammered Cast Iron
Width of Cut	-	5 1/2 inches
Depth of Cut	-	3/8 inch
Feed	-	12 1/4 inches

This is the sort of output that can be obtained from the correct design, proper material and accurate workmanship embodied in the Milling Machines and Cutters manufactured by

ALFRED HERBERT LTD., Coventry, Eng.

We carry also a full line of
High Class Machine Tools and "Velos" High Speed Steel.

Works 12 to 20 Times Faster than any other Surface Grinder

THE P & W VERTICAL SURFACE GRINDER

Pratt & Whitney Vertical Surface Grinders at work in a large Manufacturing Plant

The very strongest testimony of the real worth of the machine is the fact that in the 3½ years it has been on the market over 1000 have been sold with the demand still increasing.

The most rapid and accurate method of surface reduction known.

Grinds from the rough and gives a mirror finish.

"Bemis & Call" Combination Wrench

A successful combination of unusual strength and durability can be easily secured in this positive grip Combination Wrench.

It does the work of two ordinary wrenches efficiently.

It is made from selected materials; head, bar and shank being a one-piece steel forging.

Thoroughly casehardened. All parts are interchangeable. The best value at medium cost.

Write at once for catalogue of Wrenches

Jot This Down For Remembrance

Every Reamer you've got is making its record on your books---on the debit side or the credit side. The Reamers that always cut smoothly and accurately, enabling the workman to do the work in the shortest time are the profitable ones. Those are

"SHIELD BRAND" Reamers

They have eccentric flutes---spaced unevenly and of unequal depth, but the cutting faces are milled radial. That's why "Shield Brand" Reamers invariably do first-class work rapidly.

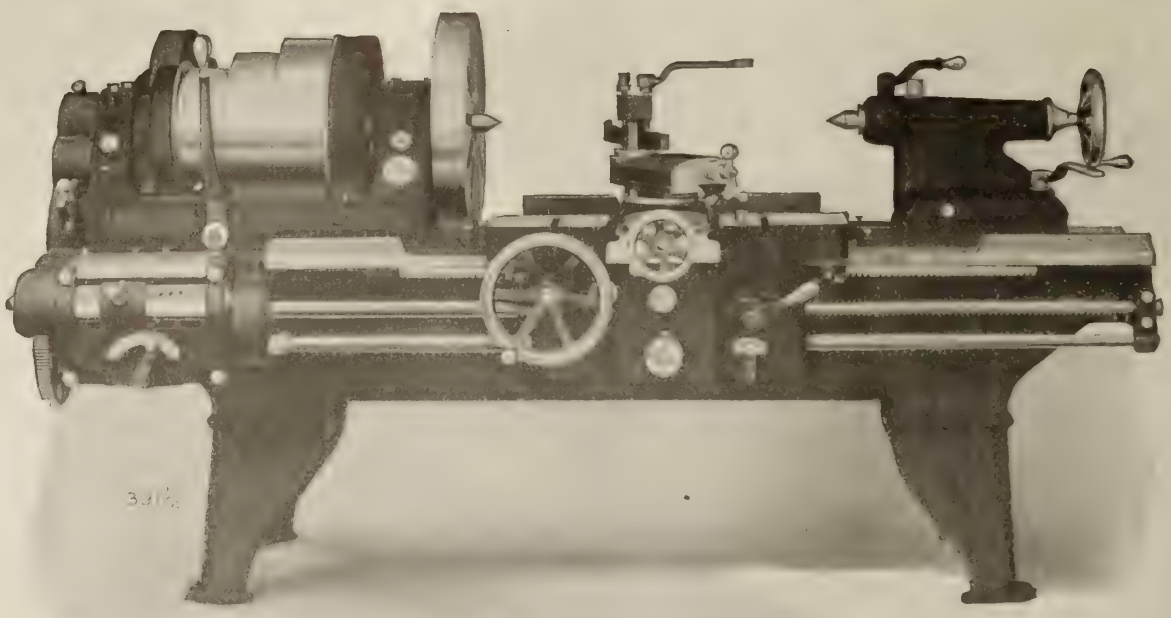
Westinghouse Motors

drive air compressors at the exact, maintained, uniform speed to develop their greatest efficiency.



Westinghouse Type CCL Induction Motor Driving Air Compressor.

Westinghouse motor-driven compressors are in every way more economical than steam-driven units, and eliminate all of the objections against steam drive. They are self-contained, receiving their power through a couple of flexible wires. They are readily moved about, are always ready for business and consume no power when idle.

Canadian Westinghouse Co., Limited, Hamilton, Ontario

TORONTO	MONTREAL	HALIFAX	WINNIPEG	CALGARY	VANCOUVER
Traders Bank Bldg.	52 Victoria Square	Telephone Bldg.	158 Portage Ave. E.	311 8th Ave. West	439 Pender Street

Cost Reducing Features

An indestructible spindle bearing made of hardened steel and cast iron.

A head construction that gives more effective pulling power at the spindle than any other lathe built.

A patent "compensating V" that permits four times the bearing area between the carriage and bed found on other lathes.

A carriage in which the tool thrust is taken on a bearing the entire length of the carriage, and which positively will not climb the V.

A double-walled one-piece apron which will last as long as the rest of the lathe.

A quick change gear complete in one unit, giving thirty-six changes with two operating levers.

An offset compound rest which can be used without skinning the operator's knuckles.

The centres set back of the middle of the bed, giving greater swing over carriage and permitting the turning of work up to the maximum swing without the tool overhanging the bed.

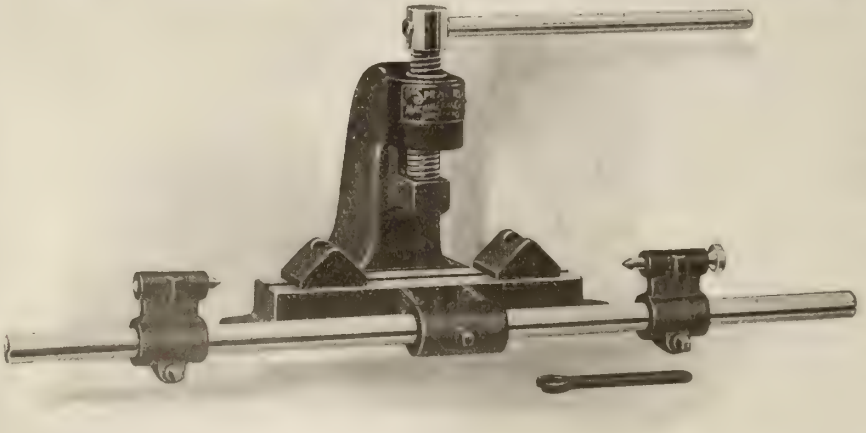
Among The Smallest In Size But The Greatest In Efficiency

Springfield
12-Inch Crank Shaper



While small in stroke this Shaper is heavy and substantially built. The same care is used in its construction as is shown in any of our higher priced tools.

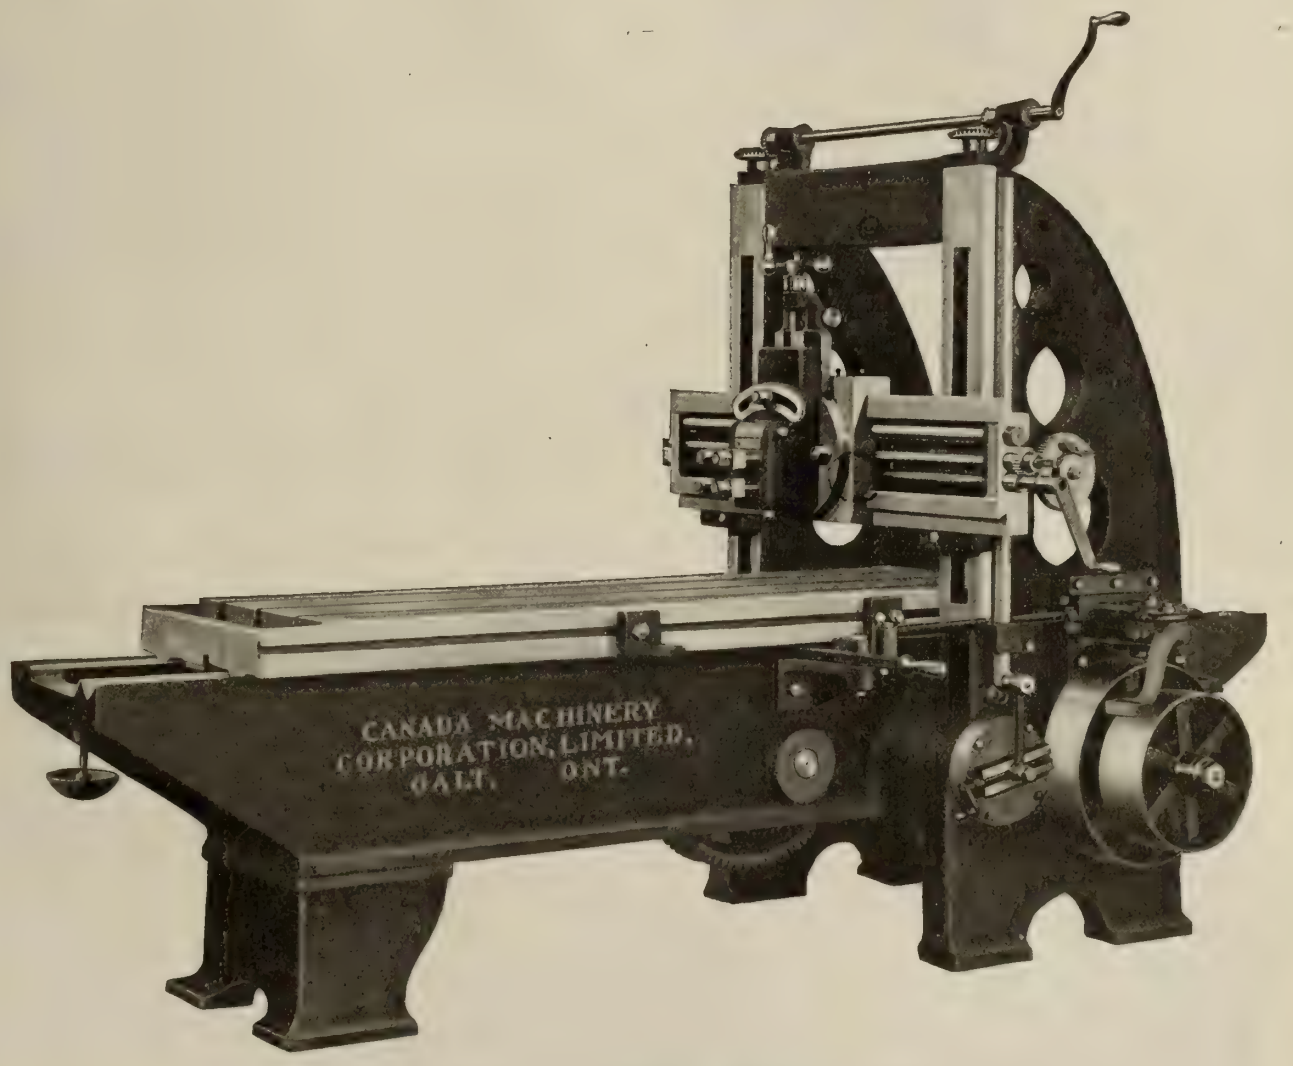
Nearly a quarter of a century's experience is back of Springfield Shapers. And our shapers are noted for their *simplicity*.

Consider these points about the 12-inch Crank Shaper. The vises have steel-faced jaws and a graduated circular base to permit of their adjustment to any required angle, and may be secured to top, face or side of the table. All the handles for operating the machine are placed in accessible positions, and so arranged that any adjustment, either of stroke or position of cross-rail, may be made while the machine is in motion. It is unnecessary to adjust the feed for different heights of cross-rail because it is made to adjust itself *automatically*. Write us for circular No. 111.

This Bench Straightening Press Saves Time and Energy

If you have our Bench Straightening Press you can straighten the work and test it right on the bench.

Compute the time it takes your men to carry their heavy loads from bench to lathe and vice-versa. Consider the time it takes to straighten work with a hammer, and the *loss* of time involved in testing it and perhaps carting it back again to be done all over.



There's only *one* sensible way of looking at the question. Our Bench Straightening Press has its own testing centres, and the fist straightening process is also the final. The work will be absolutely accurate and will remain so in the lathe. Straightened right at the bench. *Write for Circular No. 101.*

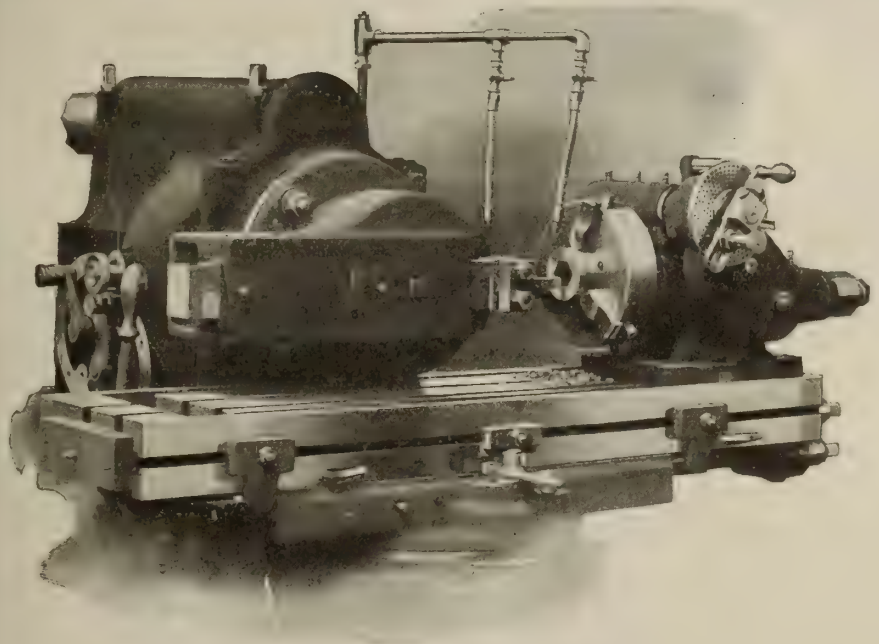
Milling Screw Machine Cams

The Cincinnati Way

This is one of the jobs that generally puzzles the toolmaker who has to do it right. The difficulty is that the great variety of cams used all require exact leads, most of which cannot be produced by any practical combination of changed gears.

On a Cincinnati you gear the Miller for one of the shorter leads. Then by setting the Dividing Head and the Vertical attachment at an angle you get a mathematical relation between the forward movement of the table, the revolution of the Dividing Head spindle, and the angle to which it is set, which produces the exact lead required.



We have figured out all the settings for you for leads, from .6 inch to 6 inch advancing by .001 inch.

You can have these tables for the asking if you are using a MODERN CINCINNATI UNIVERSAL.

The Cincinnati Milling Machine Company

CINCINNATI, OHIO, U.S.A.

Hendey 24-inch Improved Engine Lathe

IT has taper journals for spindle, annular bearings for same, and lubrication controlled by ring oilers. It has mounted change gearing, giving 36 different threads and feeds. Threads not shown on index, including metric pitches, can be cut with the aid of a few extra change gears. It has automatic stop for carriage in either direction. Reversing travel controlled by lever located at right hand end of apron, allowing the spindle to run in one direction. Carriage is heavy and substantial but has remarkably easy traverse along bed by means of hand wheel. This easy movement appeals to the operator. Workmanship and accuracy of our machines guaranteed to be the very best.

Send for complete catalogue illustrating all sizes, including Geared Head Lathes

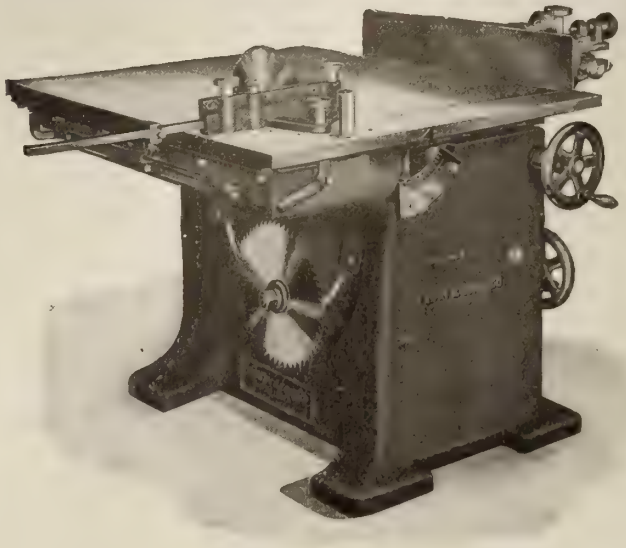
24x48" EXTENSION BED
GAP LATHES

The Rahn-Larmon Extension Bed Gap Lathes are designed to meet the requirements of repair and jobbing shops or large plants or mines that are compelled to do their own repair work.

This cut represents our 24x48 in. Extension Bed Gap Lathe, which is practically THREE lathes embodied in ONE machine.

The top bed slides along the lower one, and can be adjusted to any width of gap required within range of the lathe. By moving the upper bed, the distance between centers can also be considerably increased.



Both beds are very heavy and substantially constructed. Their entire lengths are firmly braced with girders, and thus enabled to absorb the vibration of the heaviest cut.

The sliding bed is accurately planed and fitted into the lower bed, and as the carriage and tailstock are moved along with it, perfect alignment with the head spindle is assured in all positions. The bed is moved by means of a coarse pitch screw and hand wheel at the rear of the lathe.

Write for catalogue of complete list of Lathes that are guaranteed to effect economy in your shop.

The Rahn-Larmon Co.
Cincinnati, Ohio, U.S.A.

HAVE YOU EVER SEEN A NO. 205?

No. 205. Double Circular Saw.
Patented Jan. 26, 1908.

If you did, you know it's the finest saw ever built for pattern shops.

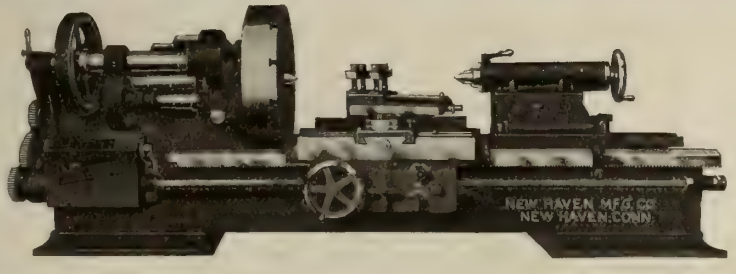
16-in Quick Change Lathe.

THE
BEST TOOLS
AT THE
RIGHT PRICE

and ***Champion Lathes*** will give you more conveniences, greater accuracy, and lasting service than can be found anywhere for the money.



In addition to all gears being safely and completely guarded in the neatest and convenient manner, they have a range of Screw Cutting for right or left hand threads of 2 to 56 per inch, including 11½, with feeds 3½ times the threads, and all obtained through a Quick Change Box with the plainest, least complicated Index Plate for finding and changing instantly all combinations without the removal or reversing of a single gear.

This is only one feature, and you should consult our **Catalogue of 10, 12, 14, 16 and 18 inch Lathes,** with or without attachments, Quick Change or Standard Type for

THE BEST LATHE PRACTICE

CHAMPION TOOL WORKS COMPANY

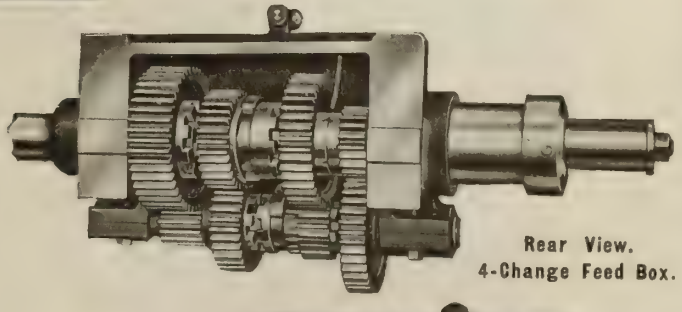
Station "B" CINCINNATI, OHIO, U.S.A.

Feed Boxes of New Haven Lathes

Absolute Reliability!

On all Lathes not equipped with a quick change gear device (except 50 in. and 60 in.) we furnish our 3 or 4-change Feed Box, which gives us our feed changes instantly, and also reduces the number of gears necessary to cut the complete range of screw heads.

We have abandoned the ordinary sliding key drive, and use multiple tooth clutches, each tooth clutch having a driving power greater than that of a sliding key.



On the coarsest threads and feeds the head screw is clutched in directly, none of the gears in the box transmitting any power.

When any clutch is engaged the others are locked in a neutral position, and the lever is so proportioned that it operates easily even while the Lathe is taking a heavy cut.

"Conqueror" Brand Profile Tool Steel

Make your own high speed twist drills, cut out the long waits and save 50% to 75% on your costs.

No Forging Required

Easily Ground

A Fluted — B Vee — C Star — D Three Wing — E Bolt Head — F Scraper — G Parting — H Twist Fluted

A FLUTED, to be used for parting and roughing tools.
B VEE, to be used for parting tools and tool holders.
C STAR, or Four Lip, is indispensable for making the following tools quickly and economically, viz.:—Chisels, Chucking or Four-Lip Drills, Counterbores, Rose Bits, End Mills, Reamers, Taps, Profiling Tools, Milling Cutters, Valve Seating Tools, and many others.
D THREE WING, wil be found of great advantage in making Reamers for cleaning out cored holes in pulleys, gear blanks, etc. As this shape produces tools bearing on three cutting edges, it perfectly roundens holes cored oval. This profile will also make fine finishing and sizing reamers.
F SCRAPER, a most valuable and handy addition to any machine shop; it will make the Scraper Tool by simply grinding into shape; will also make Three-Lip Drills, countersinks, and many other kinds of tools.
G PARTING, this will make a Parting or Cutting-off tool in almost no time, merely by cutting a piece of the bar and inserting in tool holder.
H STRAIGHT FLUTED, to be used in making Drills for Shadow-drilling or for High Speel Drills to be made at short notice. **TWIST FLUTED**, to be used in making Twist Drills. They are rolled hot to the same shape as Milled Drills and are not merely flat bars twisted, such as are sold in the market to-day under the name of **FLAT TWISTED DRILLS**. These Flat Twisted Drills, while being quite durable, cannot produce such straight and accurate bores as the drills made from our Profiles, since the latter afford a much wider bearing surface on circumference of drill, guiding the same absolutely true. **OUR PROFILES MAKE TWIST DRILLS AS ACCURATE AS MILLED DRILLS.** This refers particularly to drilling deep holes where the difference between flat twisted and our profiles becomes very noticeable.

Profiles are made fron ½ inch to 3 inch diameter running in 1-16 inch, both straight and twist fluted. Twisted Bars are made in lengths of about five feet, straight bars somewhat longer.

CUMMINSVILLE - - - - - CINCINNATI, OHIO.

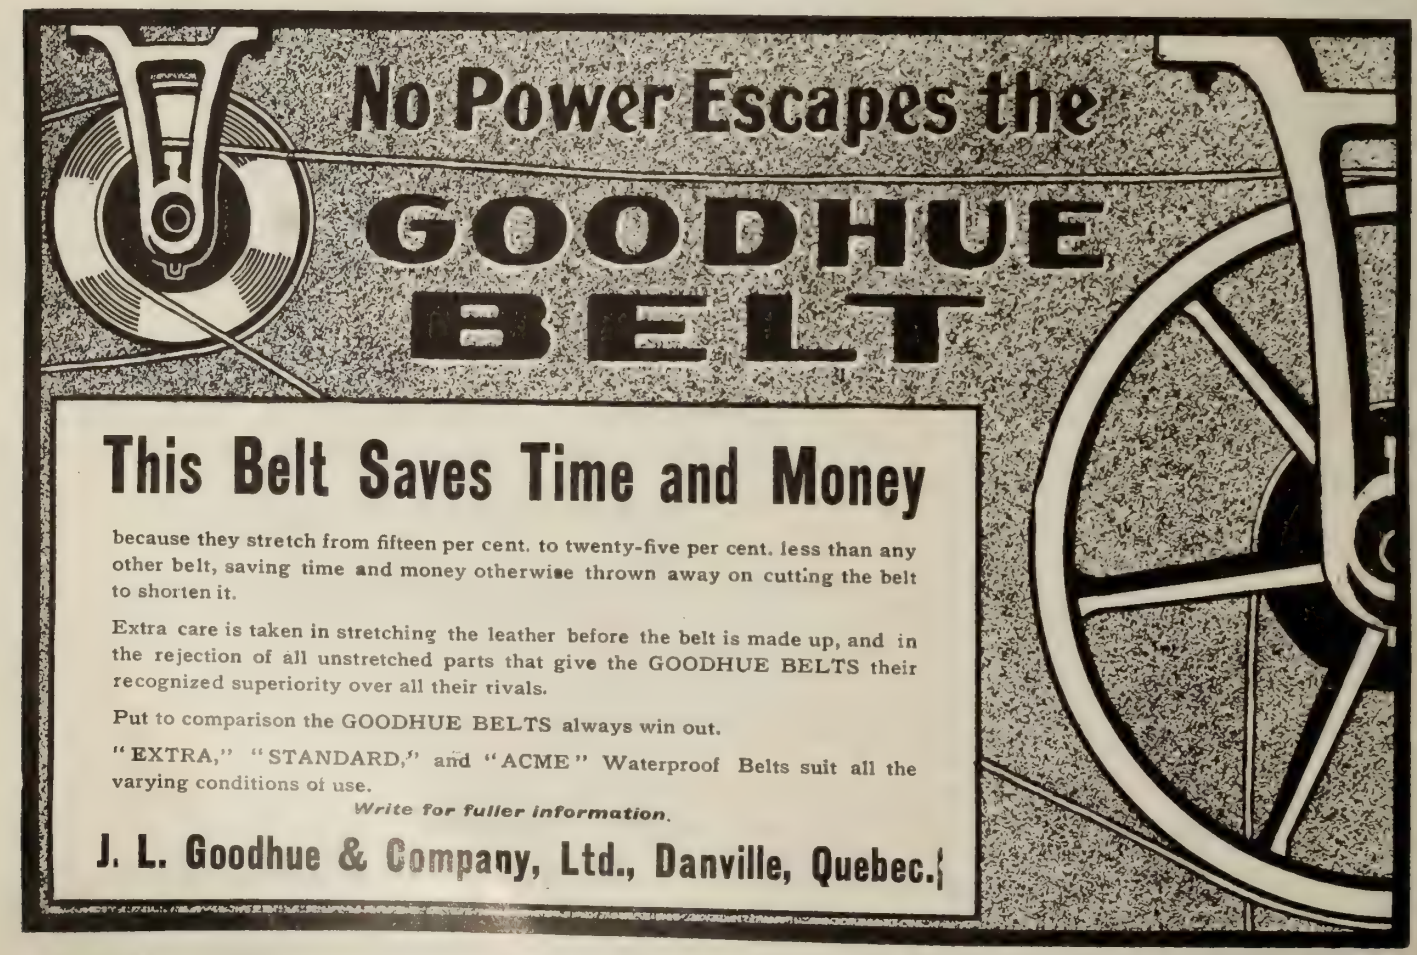
GOING SOME

Manufactured in Commercial Sizes all the way from 12 x 3 up to 120 x 48.

"That's certainly going some," a gentleman said when we told him about the 76x20 POSITIVE Combination Split Wood Rim Steel Center Pulley we have running in a mill at 8,300 feet per minute rim speed.

Well, we admit that it's traveling right smart. In fact, we don't like to put a pulley out to roll around so merrily. Yet this selfsame pulley has now been whirling at this gait for over eight months without a whimper.

A POSITIVE Pulley of the size mentioned weighs 530 lbs., against 3,960 lbs. for an iron pulley. That's why the POSITIVE Pulley stands the tremendous centrifugal force, which would burst the iron pulley. We emphasize that we combine *maximum strength and lightness.*



Bear this fact in mind. Some day you will be in the market. Then when you look over pulleys of every make, you will come to the conclusion that after all the best pulley for you is the POSITIVE Pulley, the pulley that "whirls without a whimper," because it is just so much higher grade than all the rest—the pulley that is "going some."

"IT IS RIGHT"
"WHEN WORKED RIGHT"

What a wonderful exemplification of above statement is given in the following letter :

GEORGE A. DIEMER,

Artistic and Ornamental Metal Work Made, Polished, Oxidized and Lacquered.

Magnolia Metal Co.,
113-115 Bank Street, New York, N.Y.

298 First Street, Newburgh, N.Y.,
Feb. 21, 1911.

Dear Sirs :

In reply to your letter of the 16th inst., I will say that I have used a small amount of your metal. It will be sixteen years, this coming July, that I used it on a high speed lathe (running 3500 R.P.M.) also on the countershaft hangings, **and it is there to-day**, in A No. 1 condition. There is another small shaft in the shops, a head shaft for a motor drive, which **has run much longer, and has not had a drop of oil or a speck of grease on it in at least six years,** to my personal knowledge (as I have always attended to this part myself) and it runs that freely, that even I am in doubt sometimes myself, but am willing to show it to any of your agents that care to see it.

The above will explain why I have not used much. It is right, and works right, when worked right.

Sincerely yours,
GEORGE A. DIEMER.

Special Offer

PRACTICAL ENGINEER POCKET BOOK, 680 pages, over 2,000 subjects. We do not aim to make a profit on this book, as it is an advertisement, therefore offer it at the very low price of 40c., postpaid. Many Engineers pronounce it invaluable. Address Montreal office.

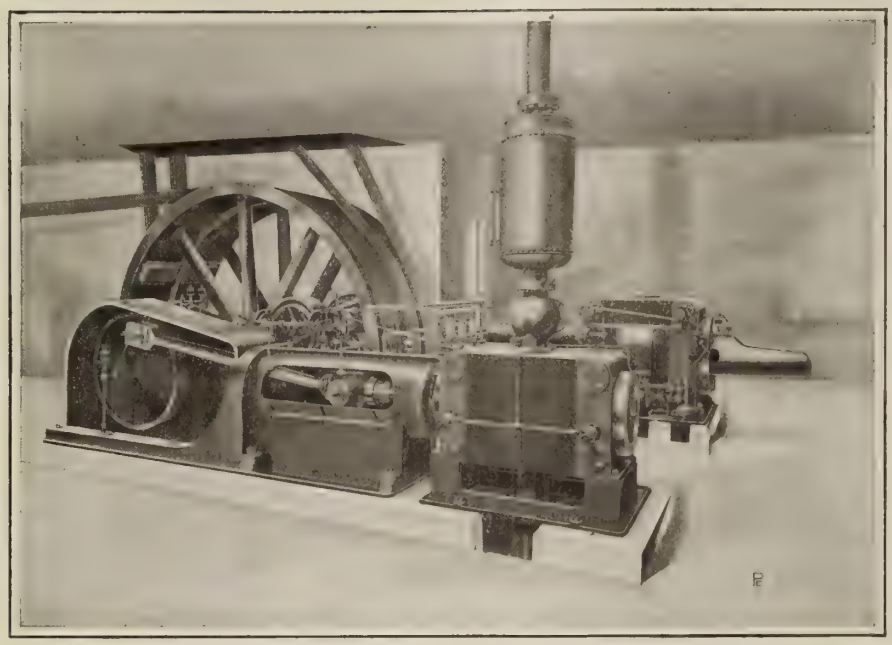
The Noon Hose Coupler



This is the only outside Coupler on the market. The advantages of an outside coupler are self-evident.

IT never blows out.
IT never freezes up.
IT never leaks.
IT saves the hose.
IT saves your compressor.
IT saves your fuel
IT saves the time of the operators.
IT needs no gaskets or washers.
IT can be adjusted and altered in one-tenth of the time another coupler can.

IT gives you the full capacity of your hose—so much so that a line of HALF INCH hose equipped with the NOON COUPLER will give practically as much power as a THREE-QUARTER inch hose equipped with any other coupler.
ITS saving qualities enable the coupler to pay for itself in a short time and will save you money from the first day you use it. WRITE FOR PRICES.

Specifications.

ALL parts are few and simple and are built to template, so that repairs can be quickly furnished. The bed is heavy and rigid, combining great strength with accessibility for all adjustments. Crosshead guides, main bearings, and face for cylinder attachment are machined in one operation. Connecting rod, of marine type, is slotted from the solid forging. Cylinder casting, of the best close-grained iron, is thick enough to permit re-boring, and has front head cast solid. The flat side valve, double ported and frictionless, is held in place by a balancing pressure plate, slotted to correspond with the valve seat. This produces additional passage to the cylinder by providing double admission and exhaust edges. Relief valves are absolutely unnecessary. Crosshead shoes have a special eccentric bolt adjustment, which is simple, rapid, and perfectly accurate. The special feature of these engines is the guaranteed control by the Begthrup Governor. This, the first successful shaft governor built, permits instantaneous regulation without flinch when changing from full load to no load.

GUARANTEE

The engine shall not run one revolution slower when fully loaded than when running empty, and a reduction of boiler pressure from the greatest to that necessary to do the work, will not reduce the speed of the engine one revolution. Any engine failing to meet this guarantee becomes the property of the purchaser upon the payment of one dollar.

OILDAG

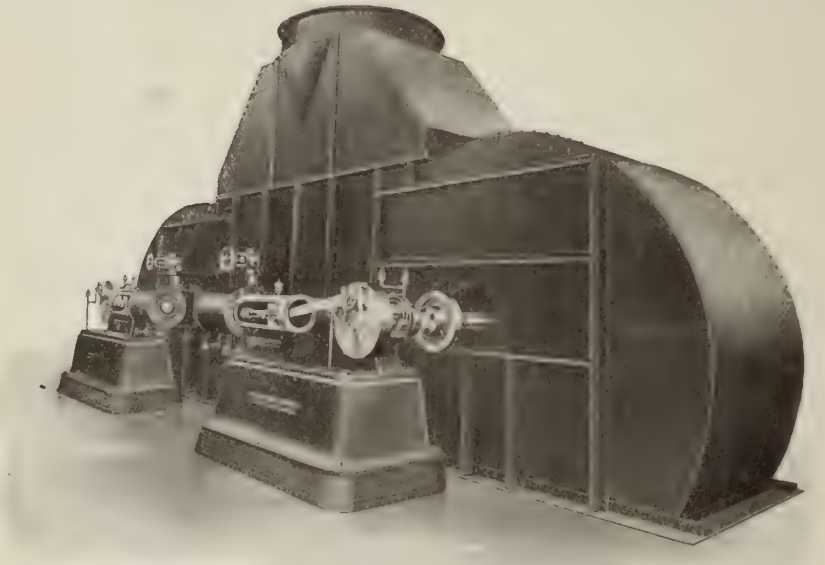
(Registered Trade Mark)
Deflocculated Acheson-Graphite, Dag and Oil.

Made in Canada.

Graphite does not dissolve in any liquid or break under pressure, and these qualities, added to the unctious softness and purity, together with its non-coalescing nature, make Acheson-graphite ideal for lubrication purposes.

The process of deflocculation takes Acheson-graphite powder so fine that 99% of it will go through a sieve having 40,000 meshes per square inch, and sub-divides each grain of this finest powder into many still smaller particles—so small that they cannot be seen through a strong microscope.

Oildag is this deflocculated Acheson-graphite suspended in oil, where it neither floats or sinks, but is evenly distributed throughout. Oildag will flow anywhere the oil alone will go.



Mr. Robert A. Ross, E.E., of Ross & Holgate, Consulting and Supervising Engineers, Montreal, writes:

"As my firm are constructing and operating steam plants, we have wished to use a mixture of graphite and oil for cylinder lubrication, but have been prevented by the fact that the graphite settled out of the mixture. **This difficulty you have overcome,** and we are now assured of the best lubrication in the world, especially in superheated steam practice."

The International Marine Signal Co. Plant and Products

By Halyard

Being an Illustrated Description of a Canadian Manufacturing Corporation, Which has, in a Few Years, by Dint of Ingenuity, Energy and Purpose, Established Itself as a Leading Provider of Navigation Aids to the Maritime Nations of the World, and a Prominent Producer of Fabricated Structural Steel Work, Steam Boilers, Tanks, Water Towers, Bridges, Hoists, Cranes, Refrigerating and General Engineering Equipment.

THE International Marine Signal Co. plant is located in Ottawa, the Capital City of the Dominion of Canada. It forms one of a number of large industrial enterprises found there, and known for their excellence of products throughout the civilized world.

Establishment of the Works.

Consequent to the discovery of commercial acetylene by Thomas L. Willson, of Ottawa, in 1892, and his successful adaptation of it to the lighting of gas buoys, the new design of which was another masterpiece evolved from the same fertile brain, works were established in the year 1907, to satisfy a world-wide demand for this new development in aids to navigation.

The success attained in the preliminary experimental and testing work was such as to insure for those concerned powerful financial support. The buildings and equipment were therefore designed and arranged to undertake all orders economically, efficiently and expeditiously. The officers and staff were selected from among those whose record showed them to be thoroughly qualified for the work of their particular department, and the wisdom of the various choices made has been amply demonstrated in the progress shown and extension of field now operated.

Fig. 1 gives a general idea of the main works building. Its total length is rather over 1,000 ft., thereby, affording one an opportunity, to comprehend the capacity available for manufacturing purposes. Railroad facilities are large, as may also be gathered from the same picture, there being no less than four companies concerned in the provision of siding service. These consist of the C.P.R., G.T.R., Ottawa Northern, Pontiac and Pacific.

Works Equipment.

Fig. 2 is an interior view of the works building, and shows various buoy bodies being assembled toward completion. Two 25 ton electric traveling cranes operate throughout the entire length of the centre bay. One 10 ton electric traveler takes care of each side, supplemented by a 5 ton hand crane. A railroad track through the centre bay, with switches to the main lines already referred to, permits loading and unloading to be done under cover and independent of weather conditions.

Fig. 3 is a picture of part of the machine shop, which contains an installation of the most modern and up-to-date tools. The equipment of punches, shears, drills and riveters, used in the fabrication of buoy bodies, tanks, water towers boilers and general structural engineering, is also the latest word in that line.

Referring again to fig. 2, it will be noted in the matter of daylight provision, that ample supply, from a good arrangement of side wall windows and roof skylights, is secured. Further, and concerning artificial light, a well laid out system of arc and incandescent lamps gives satisfactory working facilities.

Acetylene Gas Buoys.

It is advisable at this point, to say something concerning the automatic low pressure acetylene gas buoys and bea-

Fig. 1—View of main works building.

cons manufactured by the company. In the interests of humanity and commerce, every maritime nation, and every other nation having a coast line, has recognised it to be their paramount duty to provide the best possible aids to navigation.

These are of two principal kinds, first—those located on shore, and second—those afloat. Of the two, the latter is to our mind of most importance. Floating aids are usually placed outside of, or between the vessel and the danger to be avoided. Shore aids on the other hand are usually behind the danger, therefore the latter comes between the vessel and the provision for prevention.

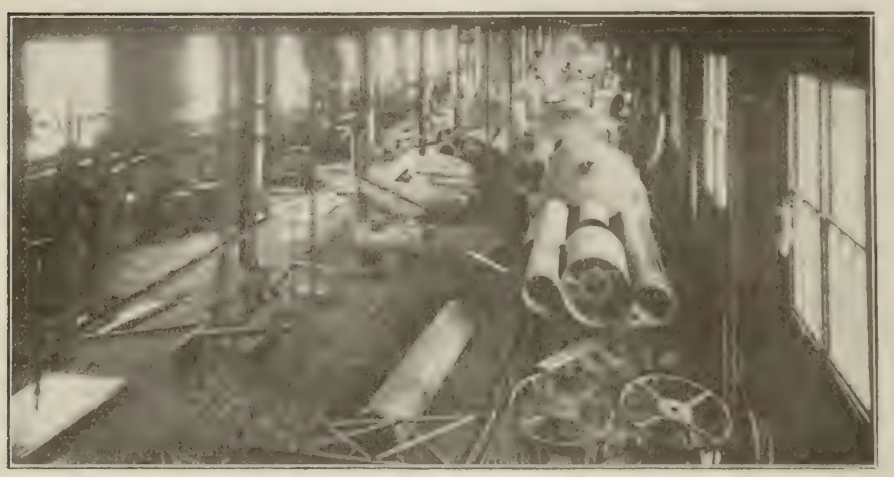

Fig. 2—Interior view of section of works.

Apart from lightships, floating signals are of two classes, first—lighted buoys; second—bell and whistling buoys. Previous to the introduction of acetylene gas, the most practical system, and that most generally used, was the storage of high pressure oil-gas in welded steel buoys. The manufacture of this gas, took place on shore in the usual way. It was then compressed into heavy steel holders under high pressure. These holders, some 4 feet diameter by 30 feet long, were then transported to each location, and the gas pumped into each buoy at a pressure of 150 lbs. per sq. inch.

Buoys lit by acetylene gas find favor with mariners, because the light is not only from 30 to 100 times stronger, according to the size of lantern, but also for the reason that its sharp penetrating effect, as compared with the oil gas-lit buoy, enables them to discern more certainly their location in thick, heavy weather.

Explanation of Acetylene Lighting System.

The lighting medium, as already stated, is acetylene gas, from which all impurities have been removed, by the use of a special purifier made for the purpose by the company. The buoys are automatic in operation, and generate their own gas under low pressure, with one full charge of calcium carbide. This latter varies in amount according to the size of the buoy, and gives a continuous light without diminution of power, throughout a period of six to nine months, without attendance.

The lantern, of best buoy type, is equipped with a Fresnel lens, which condenses the light into an intensely powerful and penetrating horizontal beam. Acetylene gas, as generally recognized, gives greater candle power per cubic foot than any other gas, at the same time the precise degree of increased strength is not perhaps too well known. Proven facts go to show that it is seven times greater in candle power than oil gas in compression, as used in the oil-gas type buoy. In addition to superiority of light over the latter, there is in addition provided a much larger supply.

The charging and recharging of buoys are simple and safe operations, easily understood, and capable of being performed in a comparatively short space of time. The system further obviates the necessity for and expense of generation, compression and storage, which form necessary adjuncts to the compressed oil-gas systems. Calcium carbide, from which the acetylene gas is generated, is contained in sealed tins, for easy transportation to each buoy location.

Explosion dangers have been practically eliminated, as the gas pressure is only a few pounds per square inch, being under any circumstance, not more than the pressure of water at the bottom of the buoy generator tube, say 6 pounds per square inch. The generator tube is constructed of heavy steel plate and steel castings, thereby making the low pressure carried absolutely safe. By dipping the calcium carbide in coal oil when charging the buoy, the possibility of even a slight explosion due to moisture affecting the carbide is entirely avoided.

Inasmuch as the buoys generate their own gas, they are independent of a convenient base of supply, an important consideration, which permits of very isolated location, if need be. There are no moving parts to the buoy, hence the absence of risk of its getting out of order, and the freedom with which it can be left unattended for long periods.

Fig. 3—Interior view of section of machine shop.

Production of Acetylene Gas.

Acetylene gas is produced by three methods. First—By bringing water into contact with carbide. Second—By dropping carbide into water. Third—By evaporation, without the water being in contact with the carbide.

For buoy lighting, the evaporation method was discarded, because considered unreliable for long periods of service in isolated positions, while the carbide to water method was decided against, on the ground that moving parts, liable to disorder, would be required. The system adopted was that of a modification of the water-to-carbide principle, and experience goes to show the wisdom of the choice, in efficiency results.

Fig. 4—Interior view of drawing office.

On land, for house lighting, railway lighting and other purposes, acetylene is sometimes used in a state of high compression. There are two different methods. One is naked acetylene compressed, and the other, acetylene compressed in the presence of acetone. Careful attention was given both these methods; but as they appeared to have very objectionable features, it was deemed unwise to adopt them for buoy or beacon use. Acetylene, while being compressed and in the compressed state, is highly dangerous; proof of this is found in the number of serious explosions involving loss of life and danger to property.

The purifier used ensures absolutely pure gas, and obviates clogging or carbonization of burners.

Types of Buoy, Construction and Operation.

Among the various buoys, beacons, etc., manufactured, are to be found the following leading types.—The combination lighted and whistling buoy, the combination lighted and whistling buoy with overhead or air bell, the automatic beacon, and the automatic beacon with explosive fog signal bell and whistle.

Combination Lighted and Whistling Buoy—The whistling device, an added feature of this type buoy, is an improvement of the well-known "Courtenay" principle. The construction and operation may be described as follows :—The float chamber of the buoy is fitted with two large air compressing tubes, open at the bottom and sufficiently long, to extend to the comparatively still water underneath the waves. The upper end of the tubes is closed, and each of the said ends is connected to a valve casing, on the top of which, a large and powerful whistle is bolted. In absolutely still water, the level of the water inside the tubes, is the same as the level of the water outside the float chamber. When the buoy rises on a wave, the air space above the water in the tubes is increased, in a ratio corresponding to the height the buoy rises, and air is drawn in through the ball check valves in the valve casing, to fill the increased space. When the buoy descends on the wave, this air is expelled through the whistle, giving a powerful blast. The amount of air available for blowing the whistle in this type of buoy is determined by the horizontal area of the compressing tubes. In the combination buoy, the area is 7 sq. ft.

This buoy is of massive and heavy construction and may be equipped with the largest sized lanterns—375 m.m. or 500 m.m. The combination of light and whistle, each of great power, constitutes a floating aid to navigation comparable only with lightships.

Lighted Buoy with Overhead or Air Bell.—In this type, the ordinary lighted buoy is equipped with an overhead bell, fixed within the lantern support. The bell is sounded by an arrangement of 4 rolling balls, running in bronze cylinders and impinging on steel strikers, adjusted at proper distance from the bell. The strikers are held in position by corrugated diaphragms bolted to the openings of the cylinders, which keep the latter water-tight, and the balls always effective. This system is adopted in locations where ice is liable to form, and is modified under other conditions, by having an overhead bell struck on its outer rim, through the medium of 4 arms, operated also by the action of the buoy in the water.

Automatic Beacons.—Beacons for locations on river banks, sea shores, isolated rocks, etc., are automatically operated by acetylene gas, their construction being such that their placing on any desired position, calls for little preparatory work. The low pressure system of gas generation is adopted, as

Fig. 5—Interior view of lantern testing room.

for the buoys, and the same features of reliability, ease of handling and duration of lighting period applies as well.

Explosive Fog Signal, Bell and Whistle.—This apparatus is intended for occasional use only, as found necessary on account of fog conditions, and consists of a bell or whistle, operated automatically by the explosion of acetylene gas at predetermined intervals.

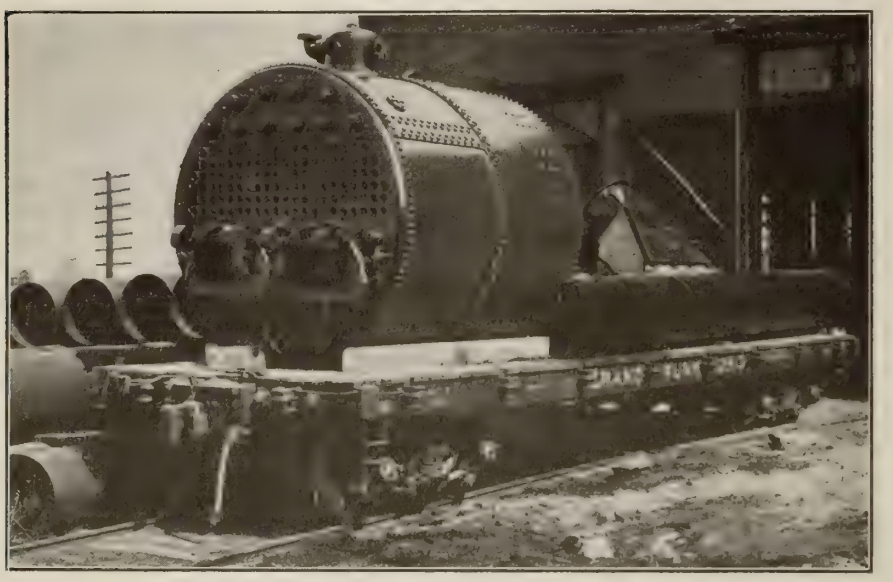

Fig. 10 Marine boiler.

Detail of Buoy Construction.

The buoy Fig. 6 consists of a gas generator tube of steel (1), supported by a steel float chamber (2), a lantern support (3), made of steel, and attached to the deck of the float chamber; a lantern (4), a purifier chamber (5), located at the top of the generator, and a counterweight (6), attached to the bottom of the generator tube, to give the buoy the necessary stability. The generator (1), has a diaphragm (7), a few feet from the bottom of the tube. The centre of this diaphragm is fitted with a conically seated valve (8), which is shown open. This valve is mounted on a valve stem (9), which passes up through the centre of the generator and through the generator head (10). The upper end of this valve stem is fitted with a hexagon nut (11), just above the generator head; the part of the stem passing through the generator head has a keyway cut into it, and a spline is fitted into the generator head, engaging the keyway, so that, when the nut (11) is turned to close or open the valve, the stem cannot turn—it can only move up or down. A stop collar (12) is attached to the extreme top end of the valve stem, with the object of preventing the nut (11) from being turned so far as to drop the valve and valve stem.

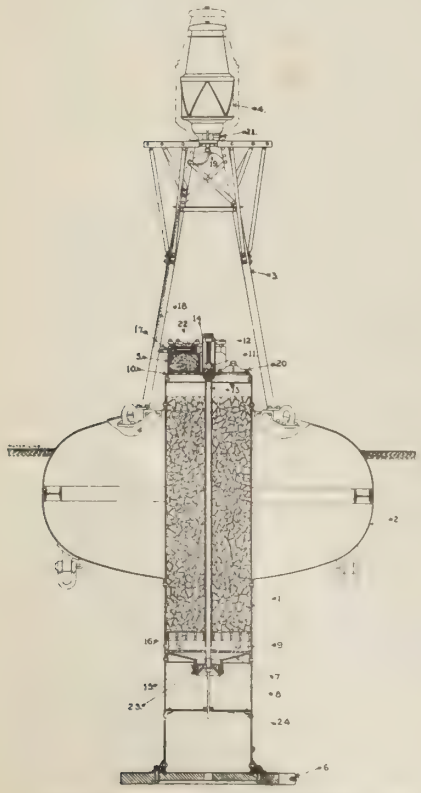

Fig. 6—Sectional view of buoy.

To prevent leakage of gas when the buoy is in operation, a cap (14) is screwed down upon the generator head against a rubber packing. This cap is long enough to permit of the valve stem (9) being raised or lowered so that the valve (8) may be adjusted to give an opening suitable for the conditions under which the buoy may be working. The valve stem is enclosed within a guard pipe (13), to protect it from the carbide, and it works through a guide bar (24), which is bolted to shelf angles at the side of the generator tube. In the centre of the diaphragm and surrounding the valve (8) is fitted a grid (23), which prevents small pieces of carbide, which may pass through the grate (16), from falling into the water and wasting their gas. This grid (23) acts also as a valve seat, and is provided with a rubber packing (15), which is held in a groove in the seat, and projects sufficiently to make a good joint with the valve (8) when it is closed, even if it be foul. A steel grate (16), upon which the carbide rests, is attached to the inside of the generator, a short distance above the diaphragm.

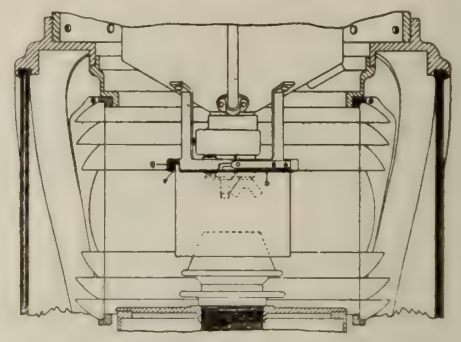

Fig. 8.—Application of Colored Glass to Lantern.

Operation of the Buoy.

The generator (1) is filled with calcium carbide in large crystals, 8 in. by 1 in., as shown in Figure 6, and the buoy placed in the water with the valve (8) open, and the valve cap (14) screwed down. The water enters the generator tube through the hole shown in the centre of the counterweight (6), and passes through the valve up to the carbide resting upon the grate. The contact of the water with the carbide immediately produces gas, which passes up through the carbide, into the purifier chamber, where all impurities and dust are remov-

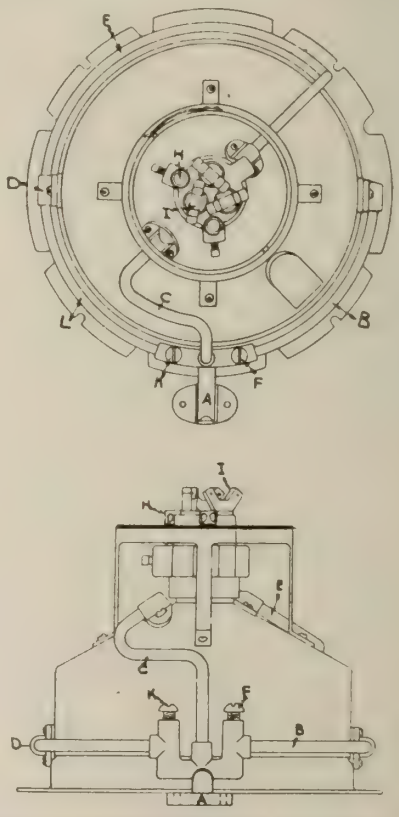

Fig. 9.—Flashlight Mechanism for Lantern.

ed ; thence it proceeds through the small valve (17) and pipe (18), to the lantern (4), to which the pipe is connected by the coupling (19).

If gas is produced faster than consumed by the lantern, it accumulates in the generator at an increasing pressure which gradually forces the water away from the carbide, and stops generation. In the figure the water is shown in this position. As the surplus of gas is consumed by the lantern, the gas pressure gradually decreases, thus permitting the water to come in contact again with the carbide, when generation is resumed. In this manner the buoy is absolutely automatic in operation. From the moment the charged buoy is placed in the water with the valve open there is always a sufficiency of gas, and never too much to cause trouble.

Lantern.

Figure 7 shows in section the construction of the lantern and the pressure regulator. The light is given by a cluster of flat flames with round pilot flames. Surrounding the burner is a Fresnel lens which give to the lantern its property of projecting a beam of light to a great distance.

Colored glasses may be applied to the lanterns without material alteration, see figure 8, which illustrates the application of colored glass to them. The glass is securely set in the inner frame A, which fits within the stand B, and is secured by a bayonet joint and locking spring C. The glass can therefore be quickly removed from or applied to, a lantern without the removal of the stand B. Red or green glasses can be fitted, as desired, and applied to either fixed or flash-light lanterns.

Flash-light mechanisms are used on these lanterns and are convertible, figure 9. A is the inlet of the gas from the lantern regulator. The supply of gas to the pilot tips H, which burn constantly, is by way of the pipe C. Pipe B leads to the flash apparatus, and, after passing through the latter, the gas is conducted through flange D and the pipe E to the flat flame burners I.

These flashing apparatus are adjusted, to give equals intervals of light and darkness, usually periods of two seconds each in the 200 M.M. lanterns and five seconds in the others. The period of darkness can be varied by adjusting the screw F figure 9, but the period of light can only be changed by increasing or decreasing the rate of consumption of gas, or by reconstructing the apparatus. When being used as a flash-light, the set-screw or needle-valve K is kept closed. Should it be desired to convert the lantern into a fixed light, simply open K, and the gas will pass directly to the burners I. On flashing apparatus the small pilot tips of the cluster serve as ignition flames, and are supplied with gas through the pipe C fig. 9 and burn continuously.

Burners.

The burner cluster is a special arrangement of flat flames to give the best effect through the lens. The main burners are of the flat flame type, and the pilots are of the round flame type. The main burners and the pilots are set into a bronze casting, which is fitted with screw conical valves for adjusting each pilot flame.

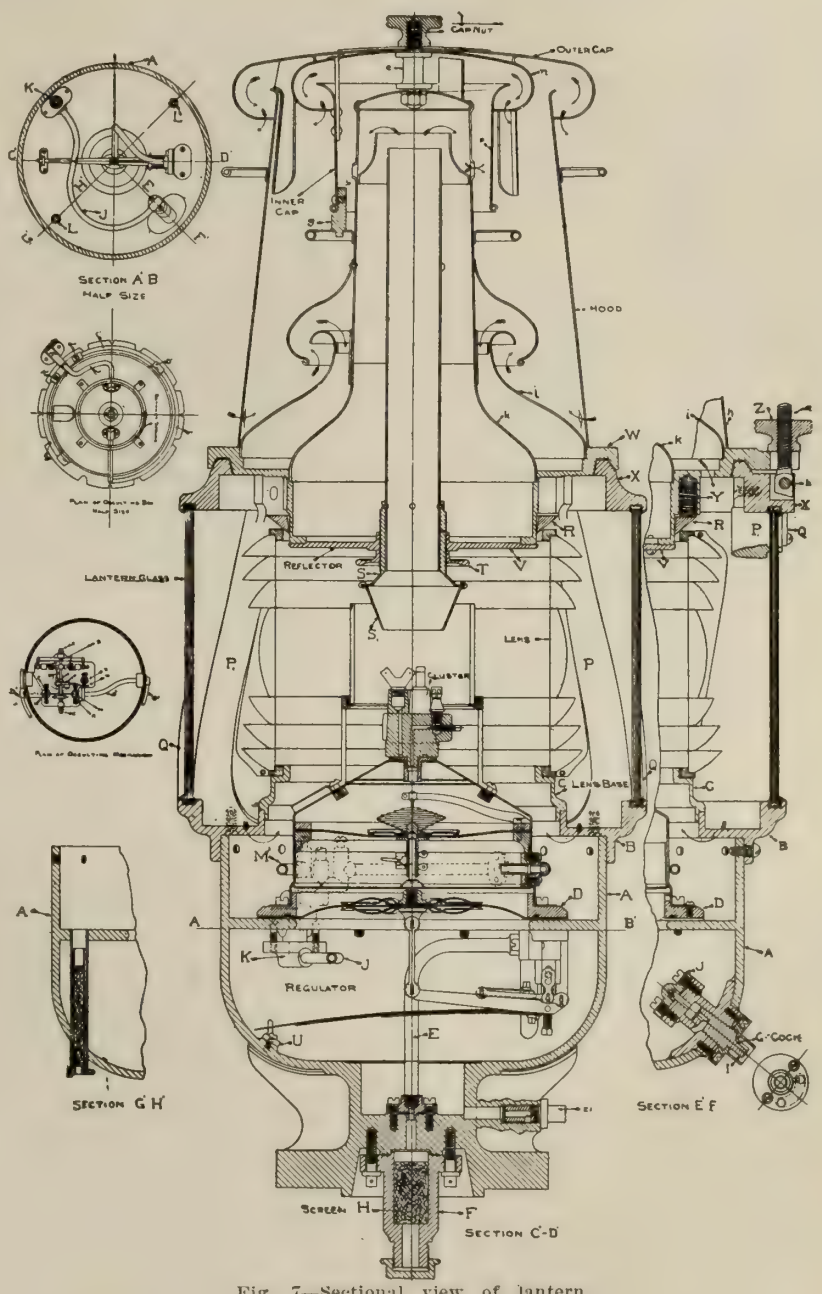

Fig. 7—Sectional view of lantern.

Designing and Testing.

Figs. 4 and 5 are interior views of the drawing office and testing departments respectively. In the former, from 10 to 12 draughtsmen are constantly employed on the design and detailed arrangement of the various forms of apparatus and equipment manufactured. In the latter, expert mechanics test and adjust the lanterns for each individual location requirement. Further, in this connection, there is provided at the shops a water tank 20x15x20 feet, into which all buoys with their full equipment are placed, and subjected to such tests as are likely to be service conditions in all weathers.

Other Lines of Manufacture.

Besides buoys, a number of other lines are manufactured and represented. Steel structural work of all kinds is fabricated and erected, while tank work, land and marine boilers, form special departments through which a considerable business is done.

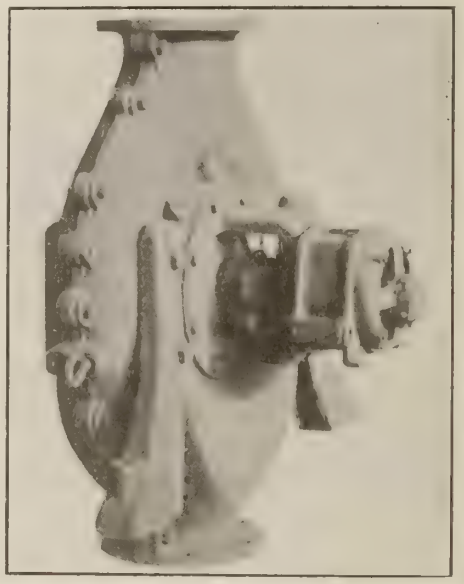
In the more strictly machinery line, crane work of all descriptions is undertaken. Filtering, icemaking and refrigerating machinery, as manufactured by the Pulsometer Engineering Co., Eng-

land, and the Petter Oil Engine, are two of the important Canadian agencies held by the company, and through both of which a profitable demand is being met.

Thomas L. Willson is president and John Bain secretary. The former, as already stated, being the discoverer of commercial acetylene and the latter a gentleman of matured business management experience in several successful enterprises. Both have been connected with the company since its inception, and much of its success and present prominence is due to their combined efforts.

CENTRIFUGAL COMPRESSOR FOR CUPOLA USE.

By Richard H. Rice, West Lynn, Mass.



THE problem of proper air supply for the operation of a foundry cupola is in many respects analogous to that of a blast furnace. The latter, however, requires much larger volumes of air, and under more arduous conditions, because its operation is continuous for many months. The foundry cupola on the other hand, is in operation only a few hours each day. Again, foundry cupola conditions are improved, due to the differences between the physical characteristics of the charge of pig iron, as compared with those of the ores charged in the blast furnace. We find the blast conditions in the cupola much more uniform, therefore the requirements for its proper operation under all conditions can be met by apparatus which produces practically a constant pressure. In blast furnace apparatus, constant volume is the prime requisite, and apparatus must be provided capable of working under a considerable range of pressure, in order to meet the fluctuating conditions.

Results From Blast Furnaces.

Centrifugal compressors, of the same general type as that which I wish to bring to your attention, consisting of one or more rotating impellers in series, taking air at atmospheric pressure and compressing it as required, to say 12 or 15 pounds average, and 25 to 30 pounds maximum pressure, with provision for a constant rate, have been used on blast furnaces for some five or six years in England and on the Continent. No machines, however, were put on a blast furnace in this country, of the type mentioned, previous to March, 1910. The first machine was put to service at the plant of the Empire Steel & Iron Co., Oxford Furnace, N. J., and was found to be absolutely adapted for the requirements of blast furnace blowing. A number of machines are under construction for similar situations of various capacities, because of the good results obtained by this first installation. Similarly, on cupola work in the iron foundry it has been found that this type of apparatus is perfectly adapted for the same reasons which make it attractive for blast furnace service.

Extreme Steadiness of Blast.

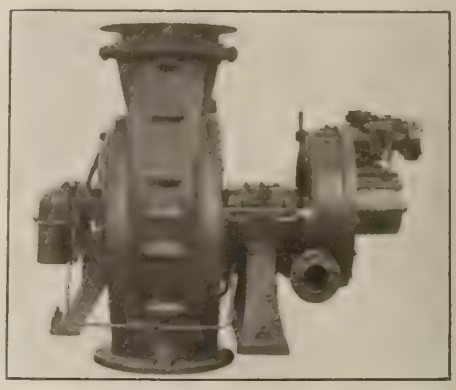
One of the important points in connection with this apparatus, is the extreme steadiness of the blast. You are, of course, aware that the steady melting of iron and the steady descent of the charge from the cupola are dependent

Type T-1-800-1-3450 Centrifugal Compressor Driven by Type Kt. 2-5 h.p. 3600 R.P.M. Induction Motor. Index E-318.64—E-312.4.

on the maintenance of uniform conditions of air pressure, because the charge in the cupola is, to some extent, supported by the pressure of the blast, and if this varies, the charge is likely to descend in a more or less irregular manner. Such irregular descent of the charge means unsatisfactory working of the cupola, therefore, the uniform, steady blast produced by the centrifugal compressor, produces more ideal conditions of melting.

High and Maintained Efficiency.

Another point of importance, is the high efficiency of the centrifugal compressor, maintained after long periods of service. This is due to improvements in design, as compared with centrifugal fans used also for this purpose, but wasteful in power absorbed. The improvement over centrifugal fans consists in changing the velocity, by a gradual slowing down of the air, in a definite manner, without production of eddies.



The apparatus is capable of maintaining its high efficiency because there are no rubbing surfaces. The impeller is the only moving part, and since it rotates with ample clearance on all sides, it always compresses air with the same efficiency. The parts which slow the air down are stationary and not subject to wear, therefore, no matter how long the machine be in operation, the efficiency will remain absolutely unchanged.

Actual Efficiencies Obtained.

As regards actual efficiences obtained, let us discuss this question in comparison with other forms of cupola blowing apparatus. I do not propose, however, to enter into technical or scientific discussions of the question, because strictly scientific comparison is difficult, owing to the fact that the positive pressure blower commonly used discharges its air in the form of a pulsation or wave at varying pressure in the discharge pipe, and is consequently difficult to test for volume. The usual method of determining the volume discharged by a positive pressure blower, is to calculate the displacement of the impellers per revolution, and from this by determination of the speed, estimate the quantity of air which is discharged. The quantity so found is called "displacement air." Such experiments as we have been able to make, indicate that the displacement air may be 15 or 20 per cent. in excess of the actual quantity delivered by the blower.

The means available to test the volume of air discharged by apparatus of this nature do not give a true average, and therefore are not sufficiently accurate to give a thoroughly scientific test. Approximations can be made, but these are always in favor of the positive pressure or reciprocating machine, since the quantities of air given are always excessive. However, if precautions are taken to measure the pressure and volume at the end of a long pipe of large capacity, so that the fluctuations in flow and pressure are reduced to a considerable extent, fairly accurate results are possible.

It is legitimate to operate blowers of different types on a furnace under exactly the same conditions, to determine their power input and furnace output in tons of iron melted. This method forms an excellent means of comparing appar-

Type T-700-72-3500-Form O Centrifugal Air Compressor Coupled to 50 h.p. Curtis Steam Turbine, from A-5, Running at 3500 R.P.M., for 110 Pounds Boiler Pressure.

atus. Such comparisons have been made between the fan blower, the positive compressor blower and the centrifugal blower, with the result that the power input required to melt down the same quantity of iron is less with the centrifugal compressor than that of the others. The positive pressure blower comes nearest to the compressor, but there is still a reasonable margin of difference in favor of the latter.

Centrifugal Compressor Superiority.

The following points of superiority are claimed for the centrifugal compressor cupola blower.

1. High efficiency. 2. Maintained efficiency. 3. Uniform, steady blast, producing steady, uniform operation of the furnace. Other advantages exist, but of somewhat less importance, such as less floor space, less weight, fewer bearings and less maintenance, because less wear. The centrifugal compressor has two bearings, automatically lubricated, which do not come into metallic contact, and, therefore, do not wear.

Description of Centrifugal Compressor.

The apparatus consists of a shaft supported in two bearings, carrying on one end an impeller of the most rugged and substantial construction, and on the other, between the bearings, the rotor of an electric motor, or turbine wheel of a steam turbine. In the case of motor drive, alternating or direct current may be used. In the case of a steam turbine the steam may be of any pressure from 100 pounds upward, and may be discharged into the atmosphere, or be run condensing. The high speed motors used are built along lines which are the result of extended experience and are reliable and satisfactory. The steam turbines are of great simplicity and high efficiency. Since compressor and turbine show best efficiency when running at high speed, their combination is most desirable.

Difficulties Encountered.

The principal difficulty met in the installation of such compressors has been that the air requirements were overestimated by the purchaser. In many cases, the apparatus installed was found to be too large. This is due to the fact that all data compiled on cupola air requirements has been based on displacement. T sts were made under my direction on a cupola melting iron in an efficient fashion, and it was found that the quantity of air required showed considerably less than that usually reckoned. For instance, the established rule in the selection of positive pressure blowers for iron foundry cupolas is based on an allowance of 30,000 cubic feet displacement for one ton of iron. This has been reinforced by computations of the number of cubic feet of air required for burning one pound of carbon to CO_2, and by the further experimental fact that one pound of coke is sufficient to melt ten pounds of iron. The computation which is the basis of the statement that 150 cubic feet of air are required per pound of carbon burned to CO_2 assumes that coke is pure carbon, which is not the case. Coke contains only about 90 per cent. carbon, and is not all burned to CO_2. A great deal is burned to CO, requiring only about 90 per cent. of the air required if the whole were burned to CO_2. The result of these qualifications is that only 80 per cent. of the theoretical amount of air above computed is actually needed. This 80 per cent. efficiency of the air necessary is also about the difference between the actual air discharged by a positive pressure blower and the computed or displacement air, therefore the rule is correct for positive pressure blowers, but not so for computations of the actual quantity needed. The tests mentioned confirm these figures. They showed that one pound of coke would melt from 10 to 12 pounds of iron, the variation being apparently due to the difference in temperature of the iron tapped off. The conclusion is that the ratio of one to ten, as commonly used, is reasonably correct.

Accurate Test Measurements.

The tests involved accurate measurements of the quantity of air passing into the cupola, and showed that 24,000 cubic feet of air was sufficient to melt a ton of iron, or 400 cubic feet of air per minute would be required for each ton per hour. This figure agrees exactly with the 30,000 cubic feet of displacement air usually assumed in positive pressure blower work at a volumetric efficiency of 80 per cent. Enough tests have been made to warrant the statement that these figures are correct, and should be used in proportioning blowers for cupolas made on the centrifugal compressor design.

Tests made by the above method on apparatus delivering a steady blast without pulsations are extremely accurate, the accuracy being such that a possible error of one to two per cent. is the limit.

A NEW HOSE COUPLING.

The Noon Universal Coupler Co., Kent Building, and 35 Richmond street E., Toronto, have introduced a hose coupling of novel design. It is one of the probably few couplers on the market, which has the hose inserted in the shank, instead of vice-versa. The method adopted has these and other important advantages. The hose cannot blow out, since the higher the pressure, the more tightly is the hose gripped. Further, the full area of the hose is always available, due to the shank of the coupling being outside instead of inside.

The two halves of the coupler are joined by a double thread of $\frac{1}{8}$ inch square section; $1\frac{1}{2}$ turns completely locking the device. Gaskets are rendered unnecessary, by bringing the end of the hose about 3-16 inch beyond the end

Fig. 1.—Noon Hose Coupling.

of the screw thread in the female part of the coupler, and about 1-16 inch in the male part. Both ends of the hose are thus forced firmly together, and make a tight joint. From this, it will be noted, that water, air, steam, etc., passing through the hose, never comes in metallic contact, with the result that risk of freezing up is reduced to a minimum.

Fig. 2 shows the method of inserting the hose. Part of the shank, in both halves of coupler, is removable, and has

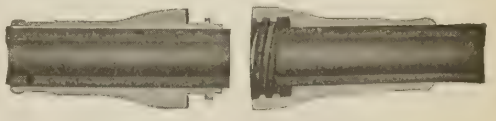


Fig. 2.—Noon Universal Coupler.

a lip at the front, which engages inside the end of the screwed portion. After the hose is inserted through the gap and the cover replaced, a wire is twisted round the neck of the shank.

H. B. Tilley, manager of the Bruce Peebles Co., Manchester, England, has left for an extended business tour in Canada on behalf of his firm. Mr. Tilley will visit all places of importance in the Dominion, and expects to be away for a year.

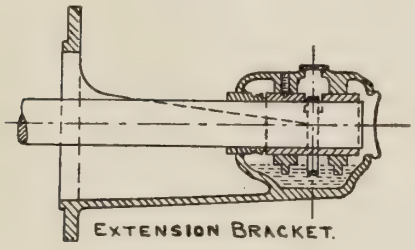
The Standardization of Design and Details

By Harold Smith, Toronto



This Article is the Third of the Series; the First Having Appeared in Our July Issue. The Writer is an Expert on Standardization Work, and Consequently Speaks with Confidence, Born of Experience. Machinery Manufacturers, on a Large or Small Scale, Will Find the Different Subjects Treated, Both Interesting and Profitable.

THE design of a piece of machinery must meet two fundamental conditions:

1.—It must be efficient, i.e., successfully perform the work required of it.

2.—It must be commercial, i.e., so arranged that it can be produced at lowest cost.

The first condition admits of great latitude in design; the second narrows it down to certain limitations, peculiar in some extent to the shops where it is to be made, and depending on the apparatus and material available for doing so. From a production point of view, a machine consists of two classes of parts those which are standard, and those which are variable; the quantity made determining into which class it falls. Thus, in a factory manufacturing only specialized lines, every part being of

Self Oiling Bearing.

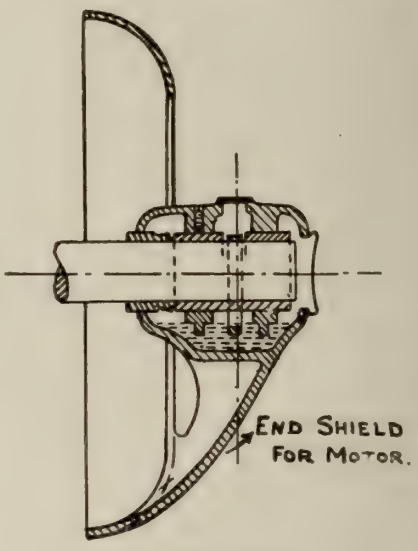
necessity handled in quantities, is standard; hence the commercial cost can be got down low, because the volume of business warrants special tools, pays for their initial cost.

On the other hand, in a factory which cannot specialise on account of handling a general business in a relatively restricted market, the machinery produced is to a large extent in variable units, and the parts of which it is composed, are as a rule, made in quantities too small to warrant much special tool equipment. Further, for a given business turnover, there is more drafting, clerical and supervision expense involved in the latter than in the former. For the one factory, $1,000 worth of business might mean 1,000 pieces put through on 10 orders, and in the other, 1,000 pieces on 100 orders. An individual order requires approximately the same amount of non-productive expense, labor and attention for a number of pieces as for one piece.

Standardization is then admittedly an important factor in enabling a shop to produce articles at a low commercial cost, and every effort should be made to introduce it where possible. At the same time, care should be taken that the fundamental idea of efficiency is not endangered.

Standardization Applications.

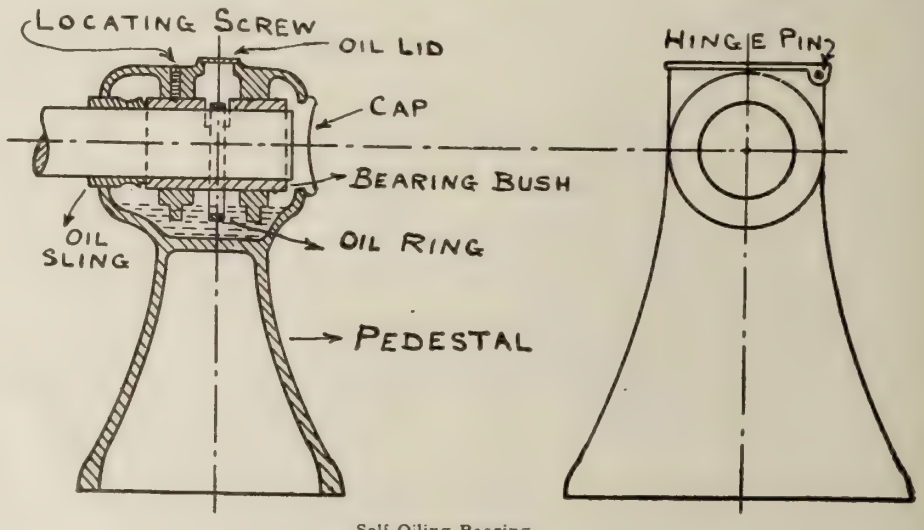
We have standardization for pieces in common usuage, which are sold under the title of supplies, such as valves, pipe fittings, etc. From their standard parts, we can build up any number of variable piping combinations. It is not suggested that a piping arrangement is a machine, but the elementary ideas of production are analogous.



We have here standard parts, valves, flanges, elbows, plugs, etc., which can be manufactured in lots. Variable items, as lengths of pipe, must be made to order. The whole forms a variable unit which will of necessity be handled in small quantities, yet by reason of the standard parts, may be produced at low cost. In a similar way, most machinery can be analysed into standard components, fundamental either to mechanism generally or to a particular machine, and into those which are variable. The best commercial design being that which uses to advantage the largest proportion of standard pieces.

Standardization does not mean an awkward looking creation, in fact rather the contrary, for it makes for uniformity of appearance, in any particular firm's product. The idea of the sectional book case, as developed by furniture manufacturers is a good illustration of the advantages of standardization. What is to them a great advantage from a manufacturing point of view, in that they can cover a maximum of combination with a minimum of standard parts (and incidentally of stock), is put to serve as a strong selling point.

Standardized Self-Oiling Bearing.



As a typical illustration of the possibilities of standardization in design, take a self-oiling bearing. This in a general way consists of 8 parts as per illustrations; of which only one need be variable. The oil sling, locating screw, oil lid, hinge pin, brass cap, bearing bush and oil ring may be kept the same, whether the bearing is carried in a pedestal or not. The end shield, extension bracket, frame, etc., are variable according to the machinery to be designed.

It is obvious that if such a scheme were carried out persistently, in course of time a demand for these standard parts would be created and warrant their be-

Self Oiling Bearing.

sing made in stock lots. Even if this be not attainable in all cases, it is a great advantage for the shop to have their

Self Oiling Bearing.

variety limited. Pattern expense is saved, and it may be noted in this particular case that the same core box will do for all the bearings.

This particular illustration would effect following economies:

Economies Effected.

Oil Sling.—This has to be machined all over (an awkward shaped profile) and shrunk on to the shafts. Made singly, it would be produced from a brass casting and machined in an engine lathe. Made for stock it can be cut from steel tube, using a profile cutter and hollow spindle lathe.

Locating Screw.—Purchased in either case, but excess quantity bought, is dead stock in one and live in the other system.

Oil Lid.—Singly, cast from wood pattern. For stock, cast 18 at a time from metal spray pattern, castings are accordingly much cheaper.

Hinge Pin.—Same as locating screw.

Cap.—Singly, a circular plate would be cut from stiff sheet brass and fastened to oil box with machine screws. For stock, all stamped, like a can lid, and from scrap sheet iron of thin gauge. No screws used.

Bearing Bush.—Singly, machined in brass lathe without special tools. In lots, use can be made of boring bars, cutters and reamers, also special expansion mandril.

Oil Ring.—Singly, in brass lathe. Castings being uneven, have to be machined all over, a fair amount of scrap resulting. In stock lots, cast from metal plate pattern, so close that they only require boring (9 at one setting) in a box chuck and touching on sides with a disc grinder. Very little scrap made.

Total saving $1.70 per bearing.

Relative Total Production Cost 1¾-in. Bearing.

Item.	Singly.	Stock Lots.
Oil sling	50 cents	20 cents
Locating screw ...	Same for both.	
Oil lid	8 cents	1 cent
Hinge pin	Same for both	
Cap	15 cents	2 cents
Bush	$2.00	$1.10
Oil Ring	50 cents	20 cents

Total saving $1.70 per bearing.

Full advantage should be taken of what can be purchased already standardized, by other manufacturers, such as eye bolts, keys, bolts, screws, brass fittings, shaft collars, dowel pins, etc., as against making them up for any job.

Standardized Carbon Brushes on D.C. Motors.

A further example which illustrates forcibly, how much can be standardized when it has to be done is the British Admiralty rule with regard to carbon brushes for direct current motors used on battleships. They allow three sizes of brush only. These are stocked by them as ordinary supplies, and served out to ships in any part of the world, without danger of misfit.

When it is appreciated, that they are buying motors from at least 25 to 30 firms and that each of these has at least 5 or 6 standard motor brushes of their own, the wisdom of the rule will be apparent. They stock three sizes, where otherwise they would have 100 to 150. Besides, there is less danger of leaving some particular ship out of brushes on a distant station. In this instance standardization makes order out of a very probable chaos.

Their standards are furthermore arranged, so that the largest brush cut in half makes 2 of the next size, and that in turn cut in half, makes 2 of the size smaller. All of the brushes are of course, rectanguhar.

The successful operation of a D.C. motor is largely dependent on its proper commutation. This is established by having width of brush, pitch of bars and volts reactance finely proportioned. It required a strong hand to force such standards on electrical manufacturers, each with their own peculiar technical points, and which in the ordinary way, they would insist on, as essential.

Summed up generally, a workshop which standardizes, is put in a position where it can "manufacture," as against one where it can only "make."

LARGE STEEL CASTINGS.

Two large and interesting steel castings were recently made at the works of the Joliette Steel & Iron Foundry Co., Joliette, P.Q. They consisted of Y pipe connections for the intake of a 10,500 horse power Doble impulse water wheel, and were to the order of the John McDougall Caledonian Iron Works, Montreal, who are building the wheel. Each casting weighed 10,000 pounds. The Joliette Steel & Iron Foundry Co. started operations at the beginning of the present year, and have equipment and facilities capable of turning out castings up to 15 tons. S. Vessot, a gentleman prominent in connection with Joliette interests, is president of the company, while J. D. Query, who has had a wide experience in steel foundry practice, is in charge of the company's Montreal office.

RAIL-LESS STREET CARS.

The first rail-less street cars propelled by electricity to be used in England have just been installed by the City Council of Leeds. The system at present is an experimental one and is being closely watched with a view to its early adoption in other cities if successful. The wheels of the new cars are fitted with rubber tires and are attached to the overhead wires by a double trolley arm. The overhead equipment cost about $6,000 per mile and the cost of each vehicle is about equal to that of an ordinary tramway car. The double trolley arm, acting on a swivel, permits of liberal deviation on either side of the road, thus allowing the vehicle to wind in and out of the traffic when necessary. Each car is made to hold 28 passengers. Only one entrance is provided and the driver sits in front in charge of the controller and steering wheel, and at the same time collects the fare from each passenger on entering.

As there is no metal track to be laid down and kept in repair, the running cost is expected to be considerably less than that of the ordinary cars. This type of car has been introduced to meet the requirements of certain outlying districts, which owing to their thinly scattered population could not maintain an ordinary service with profit. In these cases, it is thought that the system of rail-less traction with its low cost of maintenance, can be advantageously employed both to the benefit of the tramway service and the community. The city of Dundee, Scotland, is also installing a similar equipment.

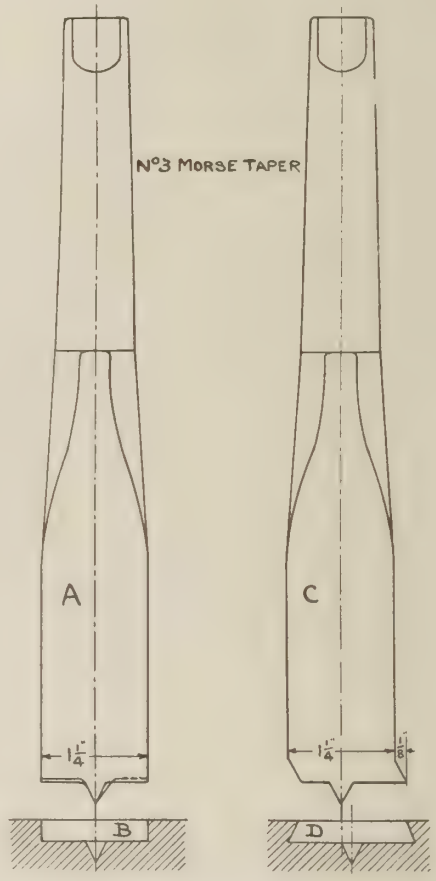
LEAD PENCIL EQUALS TWO-MILE FREIGHT HAUL.

A new method of demonstrating to employes the importance of saving small things, is set forth by the Pere Marquette Railroad in the current issue of the railroad employes' magazine. Where several other roads have shown their employes how five or ten cents a day may be saved, the Pere Marquette presents a table showing the cost of various small articles commonly wasted, in terms of mileage for a ton of freight.

Every time a postage stamp is used needlessly the company must haul a ton of freight 3½ miles. Other simple examples are: Lead pencil, 2 miles; track spike, 2 miles; one lamp chimney, 10½ miles; station broom, 35 miles; lantern 100 miles; track shovel, 90 miles; 100 pounds of coal, 20 miles; one gallon engine oil, 50 miles.

A farewell dinner and presentation was tendered K. A. McKenzie at the Engineers' Club by the Alumni Society of the faculty of applied science of the University of Toronto on the evening of August 16. He left that evening for the west. He will proceed to Vancouver, B.C., where on the 15th of September he takes up a position with a Vancouver syndicate, which is taking up the development of some large water-powers in British Columbia.

MACHINE SHOP METHODS AND DEVICES



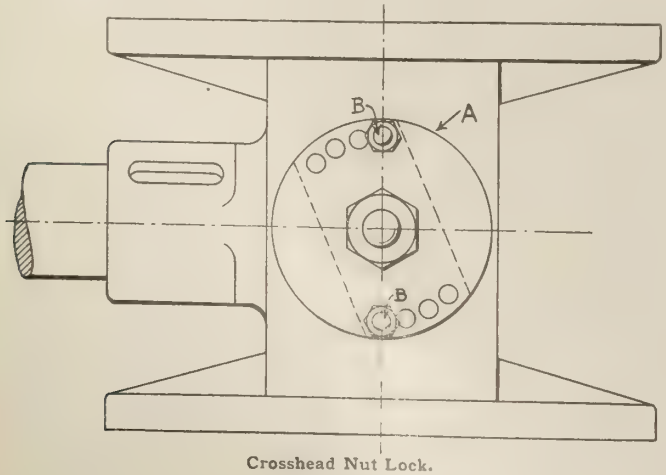
Unique Ways of Doing Things in the Machine Shop. Readers' Opinions Concerning Shop Practice. Data for Machinists. Contributions paid for.

DRILLING TAPER HOLES.

By J. H., Hamilton.

LOCOMOTIVE axle boxes are frequently babbitted on the face that goes next to the wheel hub, and one method of holding the babbit in place is to provide a number of shallow recesses which are larger at the bottom than at the top as shown at D. These recesses are generally cored out, but at the shops of the Toronto, Hamilton and Buffalo Railway, they are drilled by means of the two drills illustrated. The flat drill A, with small pilot point and cutting edge performs the first operation as shown at B, while the second flat drill C, finishes the hole as shown at D.

The point on C has no cutting edge, being round. The axle box is not secured to the drill table in any way; therefore, when the point on drill C is brought down, so as to just engage the shoulder of the small conical pilot hole formed by the cutting point of A, the box is gradually forced over under the influence of the feed until the centre of the hole coincides with the centre of the drill, and results in the offset edge of the drill cutting the side of the recess parallel with the slope of the pilot cone. In the example illustrated, the hole is 1¼ inches diameter at the top, and 1½ inches diameter at the bottom.



Drilling taper holes.

A CROSS-HEAD NUT LOCK.

By A. B., Stratford.

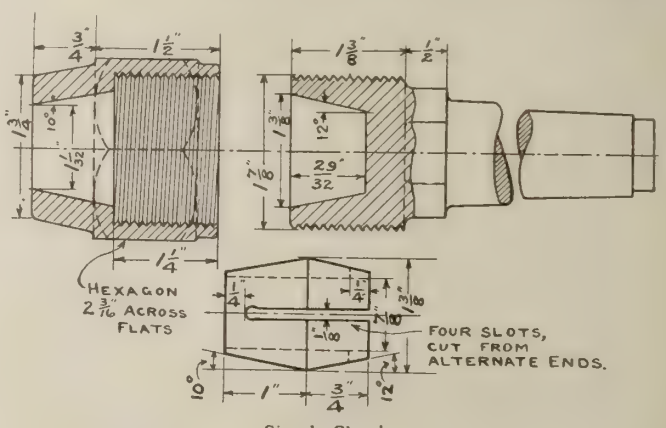
In this locking device, the circular plate A, has a hexagon cut out at the centre, which fits the nut on the crosshead pin. Two studs, B in the crosshead, prevent the plate from turning, and therefore the main nut is securely locked. The additional holes in part A, allow the main nut to be tightened up 1-24 of a complete turn, and their location is obtained by dividing the quarter circle into six equal parts, and drilling them at the first four points so determined.

Where appearance is of no consequence, a good deal of weight may be saved by cutting off the plate A, along the dotted lines..

Crosshead Nut Lock.

A SIMPLE CHUCK.

By G. L. M., Montreal.



The chuck which we describe and illustrate, is suitable for small milling cutters, chucking reamers, drills, etc. It exerts a powerful grip on the tool, and has proved highly satisfactory in service. The sketch shows the construction so clearly, that little detail explanation is necessary, beyond remarking that the bushing or collet has four slots cut to within ¼ inch of the end, to enable the screwed cap to compress it upon the shank of the milling cutter or other tool. The collet is preferably made of crucible steel, and hardened.

AN ADJUSTABLE HOLLOW MILL.

By R. A. S., Toronto.

An adjustable hollow milling tool, having an extra independent cutter is a handy appliance to have around a shop. The one illustrated, consists of a cast iron stock, Fig. 1, slotted on the face for the cutters, Fig. 7. These are adjusted by means of the cam ring Fig. 3, and a clamping ring, Fig. 4, fixes both to the face of the stock, as shown in Fig. 2.

The independent cutter is not engaged by the cam ring, but is operated by the handle and lever shown in assembly drawings, Figs. 5 and 6. Fig. 7 shows on the left, one of the adjustable cutters, and on the right, the independent cutter. The latter has its cutting edge shaped to suit the nature of the job required, and is forced down on the work, after the regular cutters have reduced the stock to size. An example of work that may be done by the independent

Simple Chuck.

cutter, is a notched shaft, shown in Fig. 8.

The tool has a large range of adjustment, with each set of cutters. Thus, a 1 inch mill, will reduce from 1 inch to 9-16 inch diameter, with one set of cutters. It will be noted, that the cutter shoulders against the cam ring at A, thereby ensuring at all points of adjustment, a solid body to securely hold them and prevent their springing away from the cut. This arrangement makes the tool quite as suitable for heavy cuts as for work requiring fine adjustment.

To adjust the cutters to size, or to remove them from the mill, it is only necessary to slacken the screws in the clamping ring, half a turn, and revolve the cam ring in the required direction by means of its knurled edge. When removing them, the cam ring is turned round, until it disengages with the grooves A. The cutters then fall down,

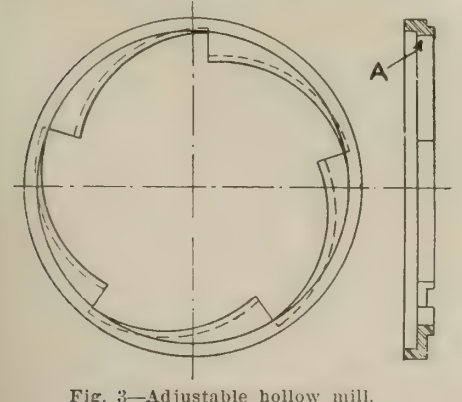


Fig. 3—Adjustable hollow mill.

and may be taken out through the centre. After being ground, they are returned to place in like manner. Graduations on the clamping and cam rings,

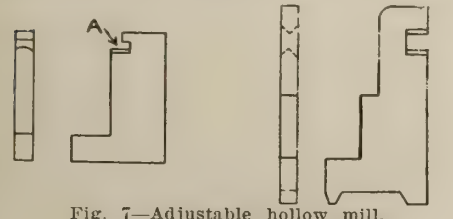

Fig. 7—Adjustable hollow mill.

make it easy to readjust cutters to the desired size.

By replacing the regular cutters with suitable dies, the mill can be made into a first-class adjustable threading die. A handle may be attached to the periphery of the cam ring, to open the dies when the full length of thread has been cut, thus saving the time and risk involved, in running back the dies off the thread. A United States patent for this device is held by R. A. Schrag, 12 Neipawa avenue, Toronto.

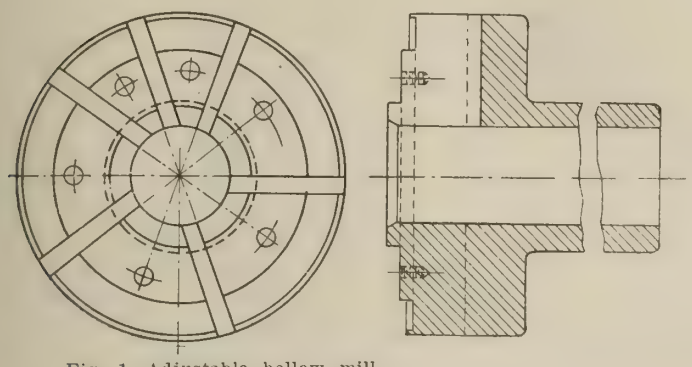

Fig. 1—Adjustable hollow mill.

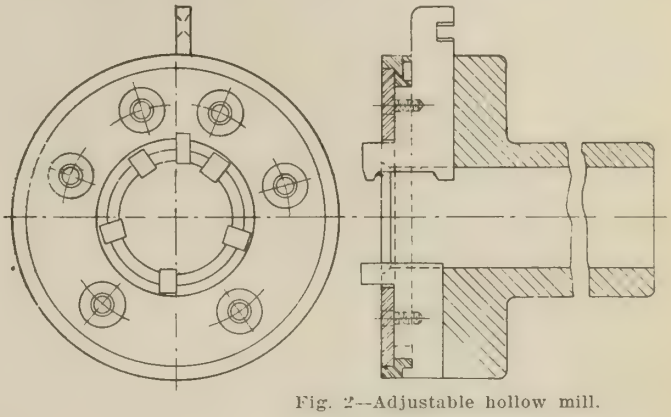

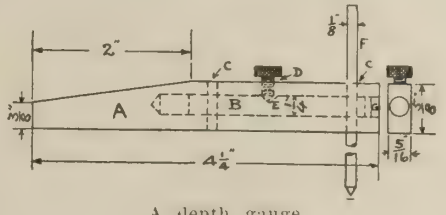

Fig. 2—Adjustable hollow mill.

A DEPTH GAUGE.

By Chas. Hattenberger, Buffalo.

The cut shows a form of depth gauge, made and found useful by the writer, in die work. The body A, of tool steel, has a ¼ inch hole drilled down its centre to a depth of about 2½ inches. B, is a piece of ¼ inch drill rod, which should be an easy fit when inserted in the above mentioned hole. C.C. are two 1-8 inch holes.

In making the gauge, one hole C is first drilled through the gauge body and

A depth gauge.

plug B. Then a piece of ⅛ inch wire is inserted to keep the latter in place, after which the second hole C is drilled. Plug B is next removed, and a hole drilled and tapped at D for a No. 8-32 thumb screw. At this point, B is replaced, and wires again inserted in holes C.C. Through the tapped hole D, mark off the position of the angular notch E, with which the point of the thumb screw engages.

It is advisable to file notch E a little

ROUGHING-OUT IRREGULAR SHAPES ON A LATHE.

By J. H. R., Hamilton.

In the accompanying sketch is shown a simple device for roughing-out irregu-

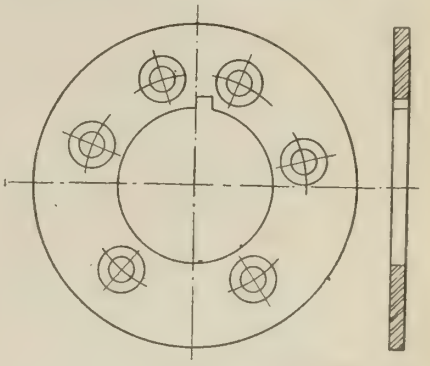

Fig. 4—Adjustable hollow mill.

lar shapes on the lathe. When turning an irregular shaped die or similar casting, the template must be tried on the work at intervals, to ensure the fit. With the device shown, the piece can be turned almost to a fit, with one application of the template.

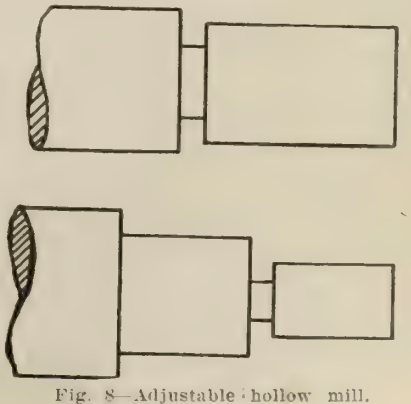

Fig. 8—Adjustable hollow mill.

A piece of heavy tin, T, is formed to fit tight on the cross-slide of the saddle, and placed in such a position, that it will clear the compound rest, when the

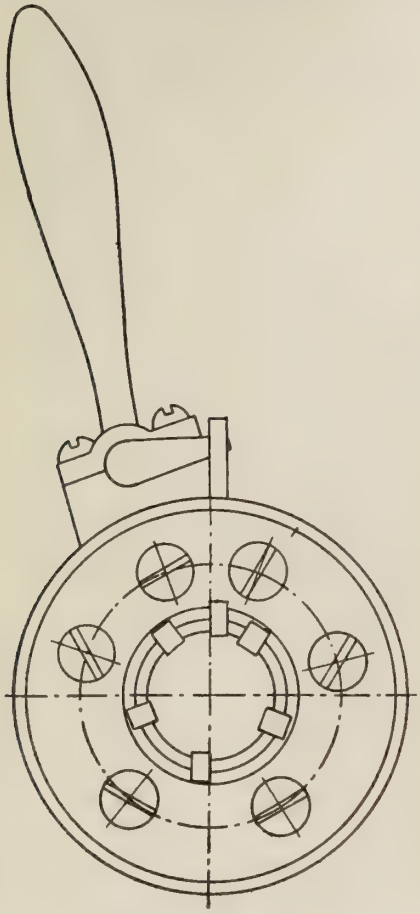

Fig. 5—Adjustable hollow mill—front elevation.

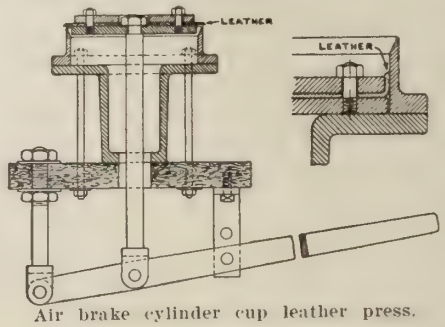
tool is cutting at the outside diameter of the work W. The outline of one-half of the template, is scribed upon this piece T, so that the axis would be in the same position as that of the work, or parallel with the shears of the lathe. A pointer P, is secured to the top slide of the compound rest R, so that any movement of the tool point, will move the pointer P in the same direction.



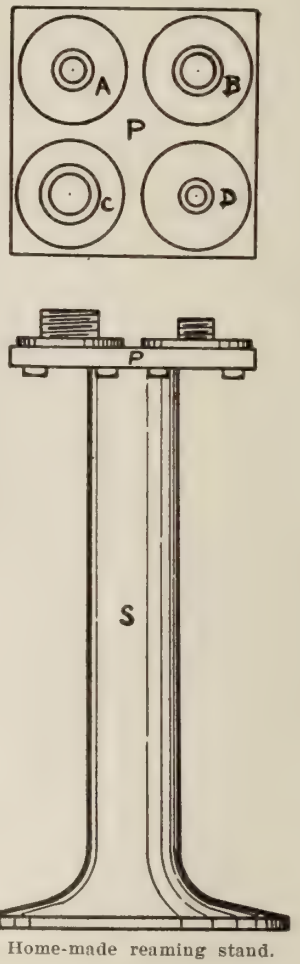
Care must be taken, to have the point of P, on the centre line of template, when the cutting tool is in the centre of the work.

Lock the saddle, and guide the tool, by following the pointer P; use the cross-feed S, and compound feed F, and the result will be the production of a very satisfactory job.

PRESS FOR AIR BRAKE CYLINDER CUP LEATHERS.

By J. H., Hamilton.

For cupping the piston leathers of air brake cylinders, most railroad shops use air, hydraulic or screw presses. At the shops of the Toronto, Hamilton and Buffalo Ry., Hamilton, Ont., a low cost and handy press, as illustrated, is giving excellent service. It consists of an old air brake cylinder cut off about two inches behind the front flange; the mouth of the casting is bevelled, and the whole apparatus mounted, and secured to a bench or table, by long bolts. The sketch explains clearly the details of the device.



Air brake cylinder cup leather press.

An ordinary brake piston and follower with the leather placed between, is forced to the bottom of the press by means of the lever underneath the table, following which operation, the leather remains in position until thoroughly set.

HOME-MADE REAMING STAND.

By D. A. Hampson, Middletown, N.Y.

No one doubts the value of a reaming stand, even if the quantity of work involving its use be not great. We had

Home-made reaming stand.

need for one in the shop, but did not feel like purchasing it. In looking around, with a view to creating something of the kind, the writer hit upon

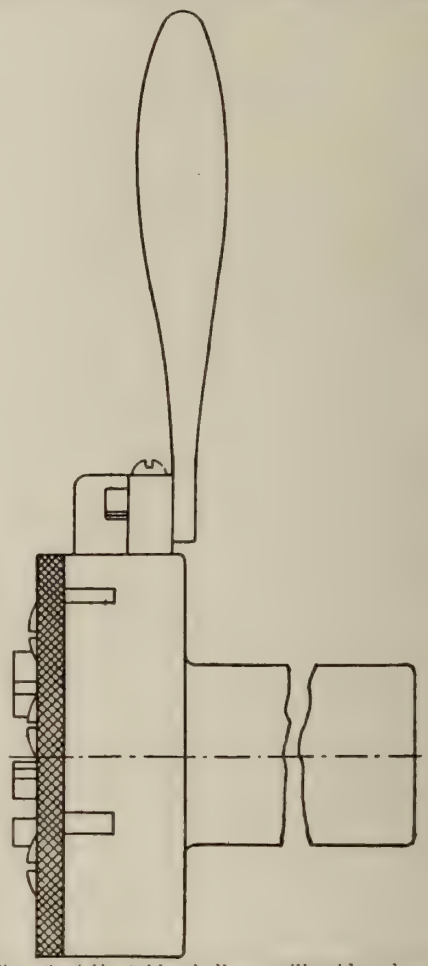


Fig. 6—Adjustable hollow mill—side elevation.

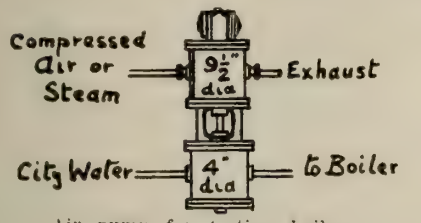
the scheme here described and illustrated.

A cast iron pillar S, which had stood unused in a corner for many years, offered possibilities equal to something that might have been specially designed for a reamer stand. It was accordingly pressed into service, and equipped as follows: Flanged castings A,B,C,D, were bolted to the square top of the pillar. Each had an upward projecting spigot with central hole, threaded outside, to correspond to the noses of our lathe spindles. When a number of pieces require reaming or tapping, a lathe chuck is screwed on to its particular spigot; the work being then chucked in the usual manner.



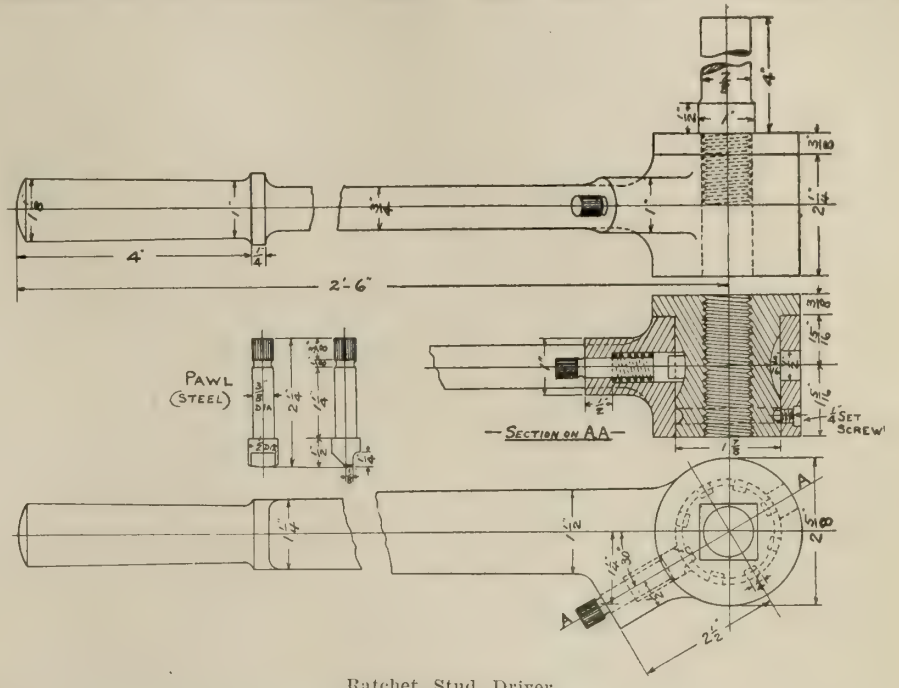
Sometimes it may be necessary to drill a piece of work, already fastened in the chuck. If so, remove the chuck from the reamer stand, and replace on the lathe. In laying-out, and small assembling work, or for holding round pieces during a number of operations, such a "reamer stand" will be found to give splendid service, and with a 3 or 4 jaw chuck, will be much more efficient and reliable than the 2 jaws of an ordinary vise.

A RATCHET STUD DRIVER.

By F. G. G., Montreal.

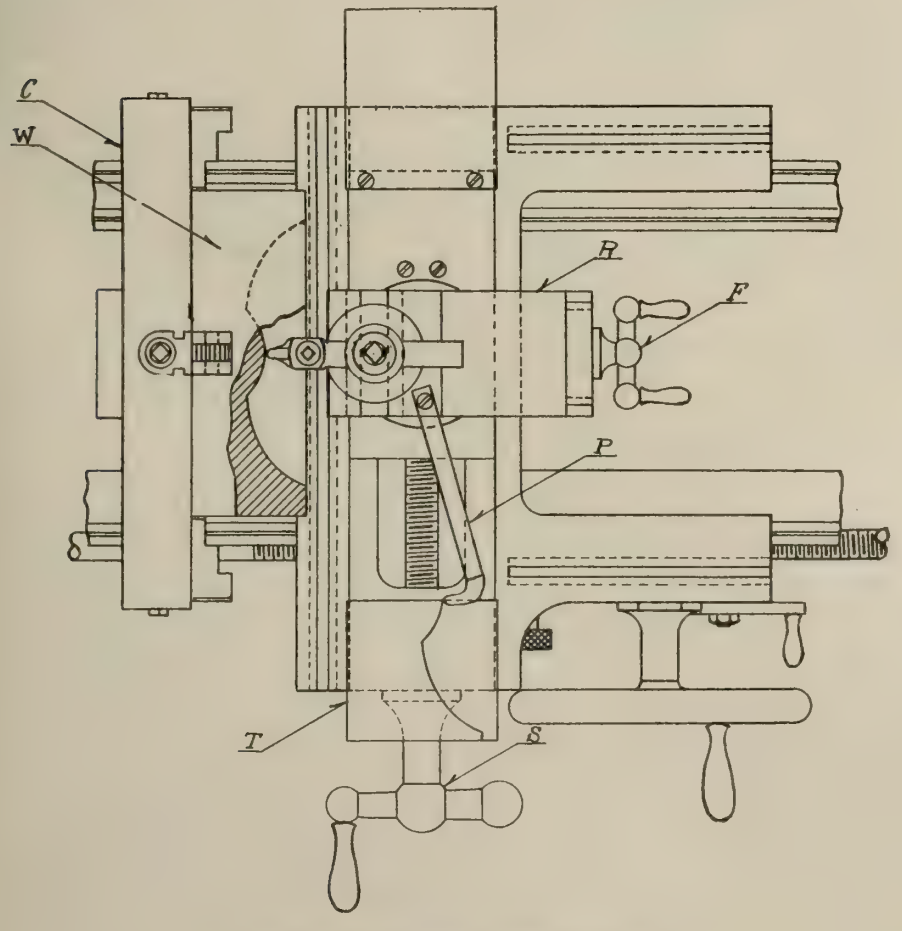
The ratchet stud driver here shown, while not new in principle, may prove useful to some readers of Canadian Machinery. The drawing being fully dimensioned, makes it possible for a tool room staff to build such a ratchet if they so desire.

When changing the socket; take out the ¼ inch set screw, raise the pawl clear of the ratchet, and remove the socket by means of the handle on top. The stud driver as shown, is well suited for the larger sizes of studs—say from 7-8 inch. upward; but for sizes smaller, it may be advisable to reduce the length of the handle, to avoid any risk of twisting off the stud.



Air pump for testing boilers.

AIR PUMP FOR TESTING BOILERS.

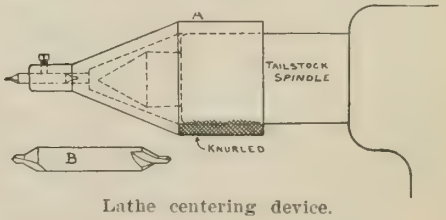


By W. F., Hamilton.

In railroad roundhouses, an ordinary 9½ inch. Westinghouse air brake pump is commonly used for applying the hydraulic test to locomotive boilers. The lower cylinder is bushed to say, 4 inches diameter, and the whole outfit is mounted on a light, two wheel truck, which can be readily moved around as required. The pump may be operated by compressed air or steam.

The suction side of the compressor cylinder is coupled to the city water supply, and the delivery side to the boiler under test. The area of a 9½ inch piston being 5.6 times that of a 4-inch piston, the steam or compressed air pressuee increases in that ratio in the compressor cylinder, therefore, the city water pressure will be multiplied accordingly.

Ratchet Stud Driver.



Roughing-out irregular shapes on lathe.

LATHE CENTREING DEVICE.

By Chas. Hattenberger, Buffalo.

The tool here shown, is easily made, and will be found extremely useful for centreing the ends of shafting, etc., in a lathe. It consists of a cup-shaped body A, made of soft machinery steel, and bored to fit snugly on the tail stock spindle. A hole drilled in the nose of body A, takes a combined drill and countersink. This latter is held in place by a set screw. The drill and countersink, drawn to a large scale, and shewn at B, are obtainable from most makers of twist drills.

Lathe centering device.

A SIMPLE OIL BURNER.

By W. H., Toronto.

The oil-burner here illustrated is used in the G.T.R., shops at Toronto for a variety of purposes, such as removal of locomotive tires, heating bent frames preparatory to re-straightening, heating

boiler patches, etc. The whole apparatus is easily portable and of extremely simple construction. The oil tank, with capacity of about 5 gallons of crude oil, is filled through a funnel fitted with a strainer, so as to preclude the possibility of choking the needle valve which controls the supply to the burner.

In front of the needle valve is a tee, into which is screwed a short length of pipe. At its end is a reducing coupling, forming a short cone, which serves to introduce atmospheric air to the oil pipe and is effective in causing a steady flow. Before this feature was adopted, it was found impossible to obtain a uniform and regular stream.

The compressed air pipe terminates in a piece of bent copper pipe, as shown in the separate detail of the burner. The issuing jet of air, creates a partial vacuum, and induces a flow of oil, which becomes vaporised as it enters the burner cone.

In taking off a tire, without removing the wheels from under the locomotive, the burner is packed-up on the rail, so that the flame strikes the tread of the tire at a small angle. The axle boxes are jacked-up, to bring the tire clear of the rail, and the wheel slowly revolved by bars to ensure the tire being uniformly heated all round. The time occupied averages about twenty minutes, depending to some extent, on the tire diameter.

EVOLUTION OF A LARGE INGOT.

By F. Walker, New Glasgow.

As a former employe of Cammell, Laird & Co., I was interested when reading the account given in the August issue of Canadian Machinery concerning the casting, slabbing and rolling of a large ingot by that firm at their Sheffield works. I have ventured, hoping it may be appreciated, to give from memory a brief description, together with dimensions and weights of the two tools used in the operations involved.

The mill built by Messrs. Cammell, from designs furnished by Davy Bros., Sheffield, has rolls of forged steel, 48 inches diameter, and 13 feet 6 inches length between housings. Each roll weighs upwards of 40 tons. The mill bed of cast steel is in 2 pieces, each of which weighs 65 tons. The housings are also in 2 pieces, of cast steel, and each piece weighs 37 tons. They are braced together at the top by a cast steel box girder, 49 inches wide, 45 inches deep, 18 feet long, and weighing about 35 tons. This crossbrace carries the screwing gear, also the steam and hydraulic cylinders for balancing the top roll. The total height of the mill is about 21 feet, its length 19 feet, and its width 13 feet.

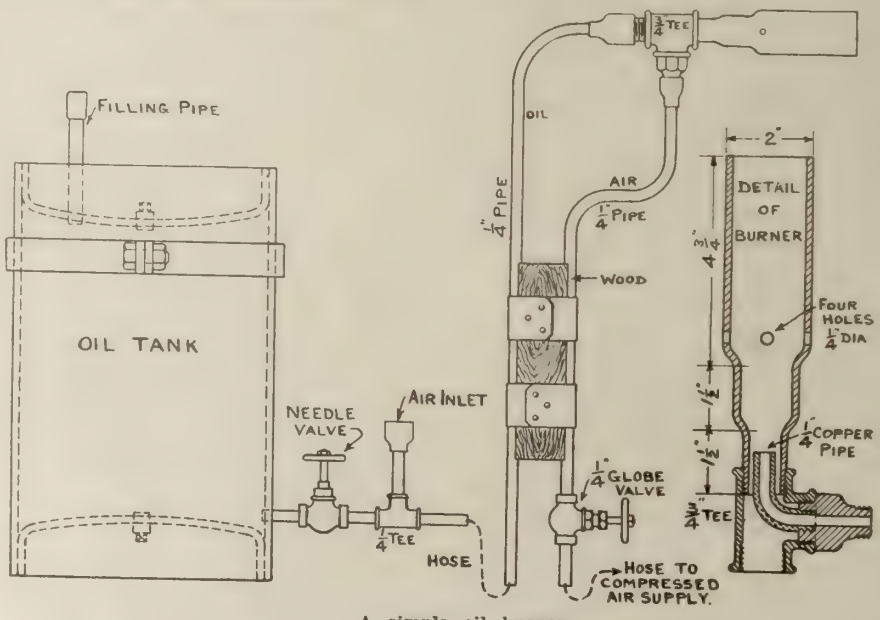
The pinions are of cast steel, 48 inches diameter, 32 inches face, and have double helical teeth. The pinion housings are also of cast steel, and weigh about 20 tons each. The forged spindles between rolls and pinions are 25 inches diameter by 17 feet, 6 inches long.

The engine, geared to the mill in the ratio of 3 to 1, is of the simple non-condensing, 3-crank vertical marine type, and has cylinders of 40 inches diameter by 48 inches stroke. Walschaert's valve gear is fitted. The engine speed is 200 revolutions per minute, and the working steam pressure 200 pounds per sq. inch. The boilers of Lanchashire type are each 9 ft. diameter and 27 feet long. The engine design and construction was the work of Davy Bros.

The hydraulic press, also constructed by them, is of the vertical 4-column type, with twin rams 36 inches diameter by 6 feet stroke. The working pressure is 2½ tons per sq. inch, which gives a total load on the anvil face of 5,000 tons. The width between columns is 12 feet.

Two steam operated overhead traveling cranes, each capable of lifting 150 tons, serve the mill and press, these being housed in the same building. The cost of equipment, accessories and installation amounted to about two million dollars.

READER, WHAT DO YOU KNOW?



Among readers of Canadian Machinery there is a clearly defined sincerity of desire to know how each overcomes the daily tasks of the machine, pattern and blacksmith shops, the foundry and boiler shops. It is believed that your methods and devices, while good, may be improved, and thereby made more valuable if you publish them, so that other brains may work on them. We will provide the setting and pay you for the material. When your fellow tradesman puts the superstructure on your foundation, we pay him and pass the "kink" on to you, free. Get into the game.

TOOTHLESS SAWS FOR CUTTING STEEL.

The employment of high-speed revolving mild steel discs for cutting hard steel is coming into general use. The discs are preferably made of boiler plate quality, about a quarter of an inch thick. They revolve with a peripheral speed as high as 20,000 feet per minute. One of these discs will cut through a heavy channel section of hard steel, 12 by 6⅜ inches, in fifteen seconds.

It appears to act by local fusion. The very high speed causes thousands of inches of surface to impinge in rapid succession on the metal undercut, so that its temperature at the point of contact becomes very high. The disc, however, owing to the large surface area, remains relatively cool. All its frictional energy is concentrated on an extremely small area of contact. The work is done so quickly that the heat has no time to spread to the metal undercut, and the sides of the cut portion are only a little warmed.

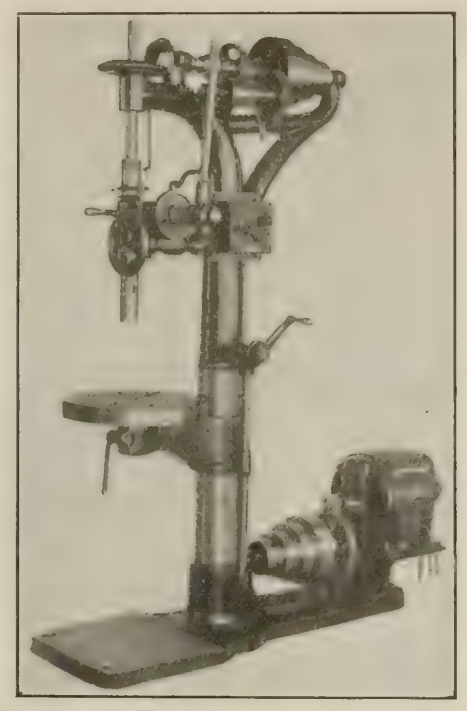
Mr. W. Franklyn Evans, who has been chief engineer for over two years for the Expanded Metal & Fireproofing Co., Toronto, and their successors, Steel & Radiation, Limited, has resigned to join Mr. Geo. W. T. Nicholson, general contractor of Montreal.

A simple oil burner.

DEVELOPMENTS IN MACHINERY

A Record of New and Improved Machinery Tending Towards Higher Quality and Economical Production in the Machine Shop, Blacksmith Shop or Planing Mill.

27-48 INCH EXTENSION BED MOTOR-DRIVEN GAP LATHE.

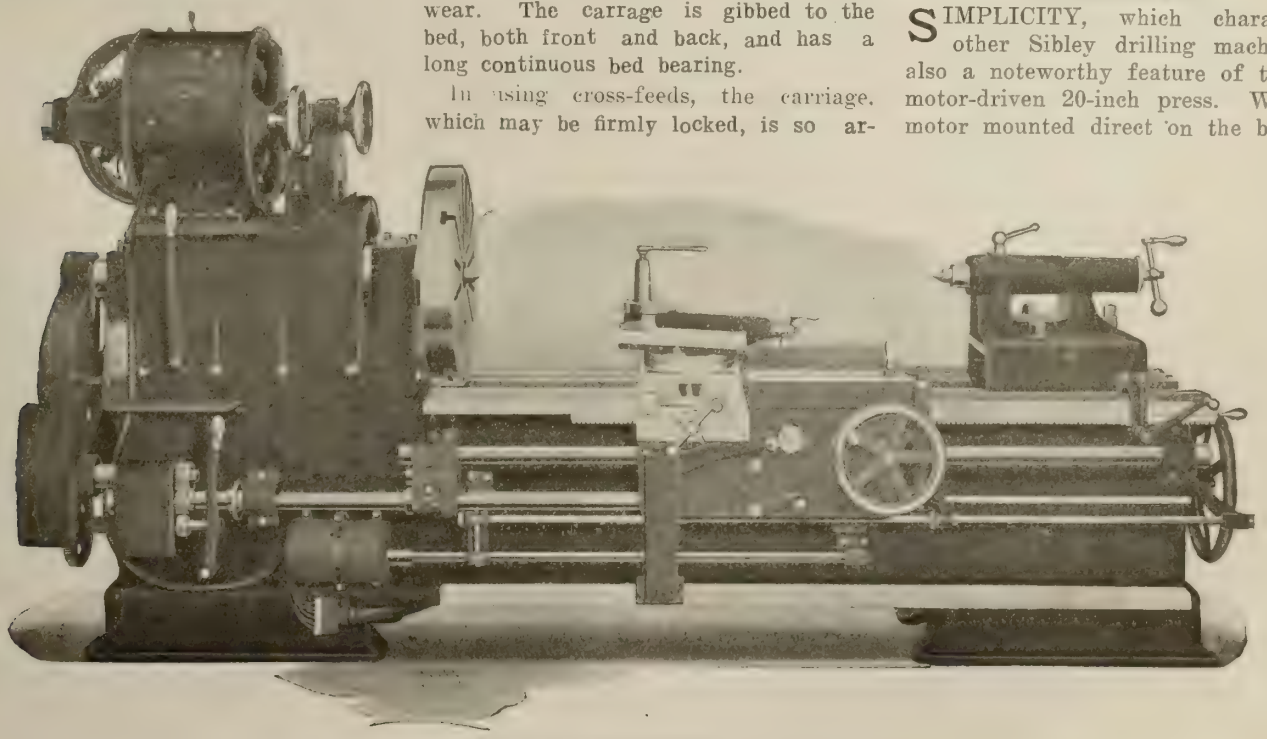


THE Rahn-Larmon Co., Cincinnati, O., are manufacturers of the electrically-driven gap lathe, shown in the accompanying illustration. It is also built for belt drive. This type lathe being particularly well adapted for repair shops, an electrical drive is desirable, aside from its inherent advantages, in that it enables location to be in an isolated part of the shop, if need be, and where transmission of power by shaft and belt, would be impracticable.

The motor, variable or constant speed type, is attached so as to conform to the general design, and power is transmitted directly to the spindle through gearing. To eliminate vibration at high speed, the motor is mounted as close to the spindle as possible, and the entire headstock, as well as the change gears, are covered, to protect the operator. Starting and stopping of the motor is controlled by a lever, mounted on the right side of the apron, and within convenient reach.

The general design of the lathe is intended to ensure rigidity, with simple construction. The extension bed top, can be adjusted to any width of gap, within the range of the machine, by means of the handwheel on the right, operating a screw of coarse pitch. Both main and top beds are extra heavy, and the sliding bed is accurately planed and fitted, thus ensuring accuracy of alignment, between spindles and carriage for all positions. The spindle is hollow, and made of special carbon steel. The boxes are made of best gun metal, and provided with means for taking up wear. The carrage is gibbed to the bed, both front and back, and has a long continuous bed bearing.

In using cross-feeds, the carriage, which may be firmly locked, is so arranged that the tool-rest can be brought close up to the gap when necessary. The front of the carriage has an extension, firmly braced, as shown, thereby allowing extra travel for the tool-rest, so that the tool may operate on the largest diameter capable of being swung in the gap. The apron is simple in design, and all gears, including the rack, are of steel. The stud pins are hardened and ground. A large range of longitudinal and cross-feeds are obtained by shifting the change gear lever attached to the feed-box; further, the feeds are so arranged, that no two can be thrown into operation simultaneously. A safety device prevents breaking of the feed-box or apron gears, either through accident or carelessness. The compound rest and cross-feed screws have graduated micrometer disks.

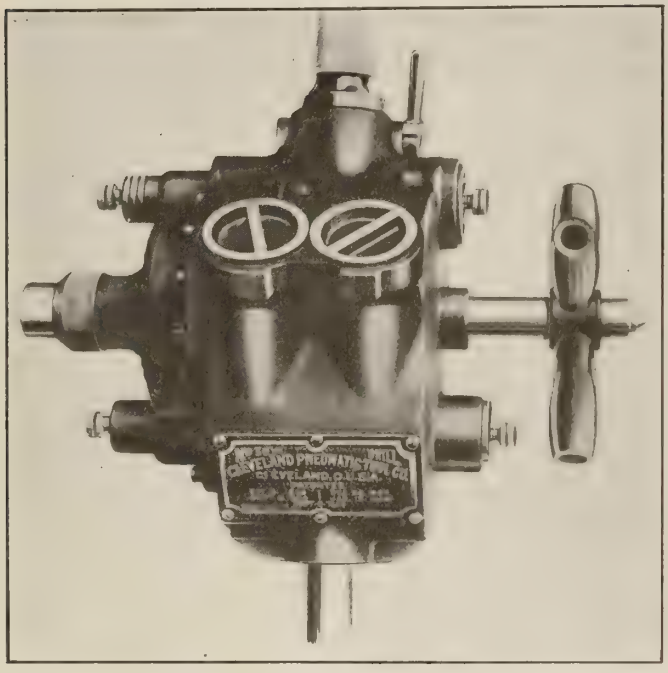


The equipment regularly furnished with this lathe includes countershaft, steady rest, follow-rest, large and small face plates, wrenches, and a full set of change gears. Additional equipment, furnished as an extra, consists of taper attachment, extension turning rest, turret on carriage, chucks, turning tools, face plate chuck, or special tool-rest. The lathe has a swing, when in the closed position of 27 inches, and 48 inches through the gap.

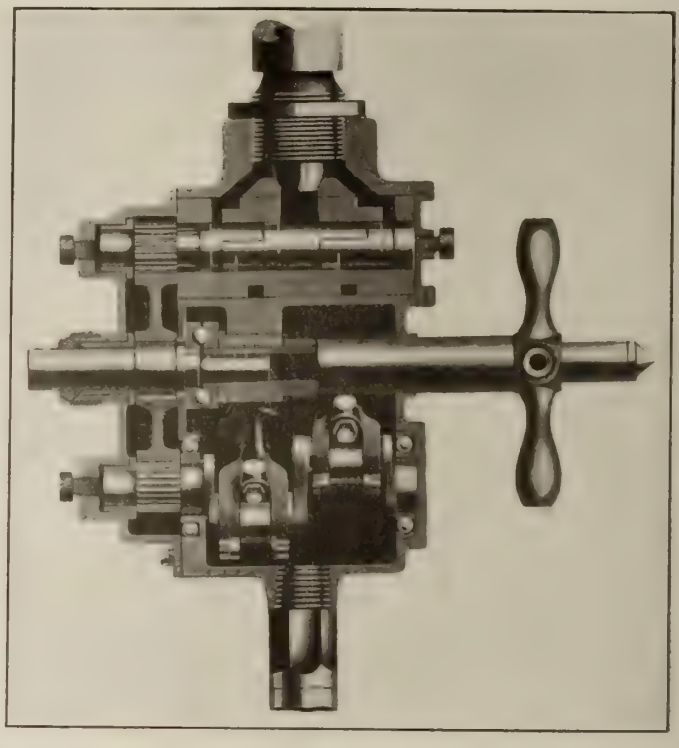
Sibley Motor Driven Drilling Machine.

SIBLEY MOTOR-DRIVEN DRILLING MACHINE.

SIMPLICITY, which characterizes other Sibley drilling machines, is also a noteworthy feature of this new motor-driven 20-inch press. With the motor mounted direct on the base and



Rahn-Larmon Motor Driven Gap Lathe.

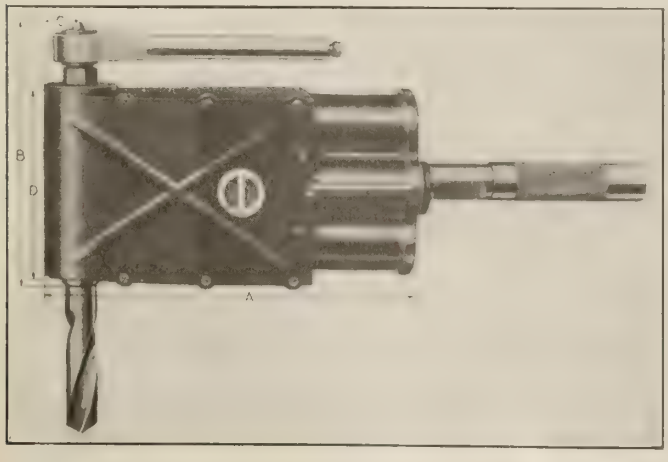


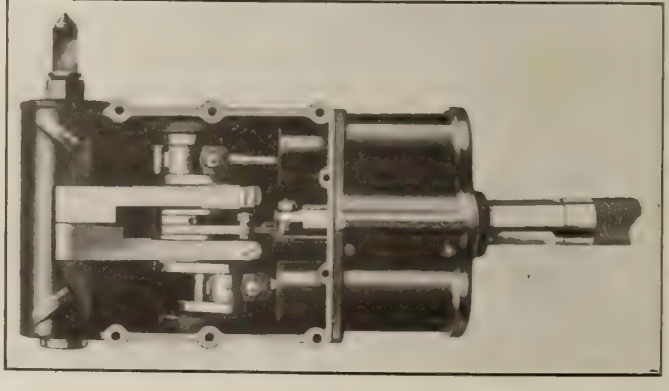
driven through gears, the weight is kept down low, thereby adding to the general stability.

Substantial design and generous proportion of working parts is a feature throughout. A 9-inch driving pulley on the 20-inch and a 10-inch on the 22½-inch drill, carrying a 2¾-inch belt, together with large cones and back gears of about 4 to 1 ratio, and 2 to 1 driving gears, deliver ample power to the spindle. The feed worm gear is driven by a steel worm running in an oil bath, which insures constant and thorough lubrication to these vital parts. The steel feed lever is light enough for sensitive, quick drilling, and at the same time strong enough for heavy work. Changing from lever to wheel feed is effected by a slight twist of the lever, and both feeds are independent of one another. An adjustable automatic stop collar on spindle sleeve trips a latch which releases the worm box lever, and the entire mechanism swings away from the worm gear on a hinge pin. A means of taking up the wear on the worm or worm gear is provided by this worm box lever.

The vertical feed shaft is driven by a worm gear and worm, running in oil, the latter deriving its power from the top shaft through cone pulleys. There is practically no spring between the head and table arm, both parts being designed strong enough for heavier work than the capacity of this press. Particular care is given to the matter of finish, the spindle and sleeve being ground, some parts polished and all rough places painted with egg-shell enamel. These machines are built with and without back gears or power feed, geared or belted motor drive, reversing countershaft or geared tapping attachment.

The weight of the machines is 650 and 900 pounds, and their floor space 17 by 45 inches, and 18 by 48 inches, respectively.





Cleveland 4-Piston Air Drill.

CLEVELAND FOUR PISTON AIR DRILL.

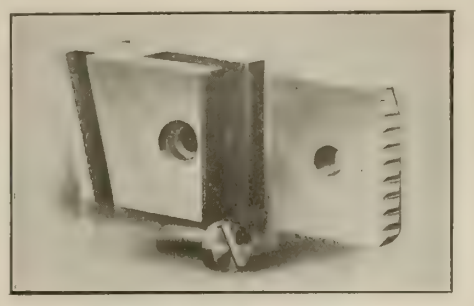
THE Cleveland Pneumatic Tool Co., Cleveland, Ohio, have recently placed on the market, an improved type of four piston air drill, which embodies several new features of interest to mechanics. Fig. 1, is an exterior view, showing a one piece body and lever reverse It is made with throttle handle reverse, or non-reversible as desired. Fig. 2, shows an interior view of the machine.

The dominant feature of this new drill is the mounting of the crank shaft upon annular ball bearings of the silent type, in lieu of the plain bronze bearings previously used in drills of this class.

Cleveland Corner Drill.

These new bearings practically eliminate all friction and wear, prevent heating, and maintain the driving crank in a fixed position, thereby eliminating lateral motion which is so detrimental to pinions and large gears.

The valve of rotary duplex type, is placed between, and equi-distant from each vertical set of cylinders, and being gear driven, supplies air power automatically to each set of cylinders without variation. The body is a one piece steel casting, provided with hand holes, through which access is had to the crank and connections. The pistons are secured to the connecting rods, by a ball and socket joint, which allows of universal motion, adjustment of wear,



The National die sharpener.

or renewal of individual parts. The gears are enclosed in an individual chamber, separated from that of the crank by an aluminum shield plate, which protects them from accident, and admits of separate and permanent lubrication.

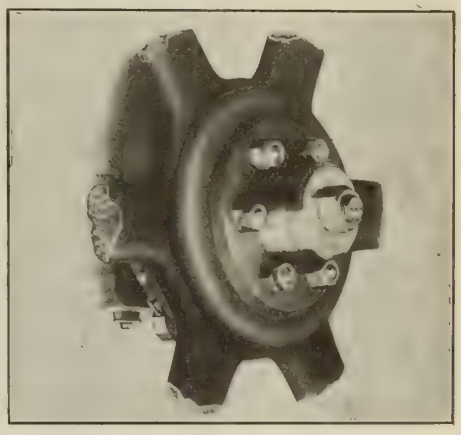
CLEVELAND CORNER DRILL.

Fig. 1, shows an exterior view of the Cleveland Corner Drill, for close quarters drilling. The machine is designed to drill or ream, within one and one eighth

National interchangeable case die.

inches of a side wall or corner. Fig. 2, shows the interior construction.

The motor consists of two double acting pistons, coupled to a crank shaft mounted upon annular ball bearings. Eccentric discs connect by eccentric straps to two piston valves, which control one cylinder each. Power is transmitted to the spindle, by ratchet arms connected to opposite wrists of the driving crank, their opposite ends alternately engaging ratchet teeth cut on the spindle.

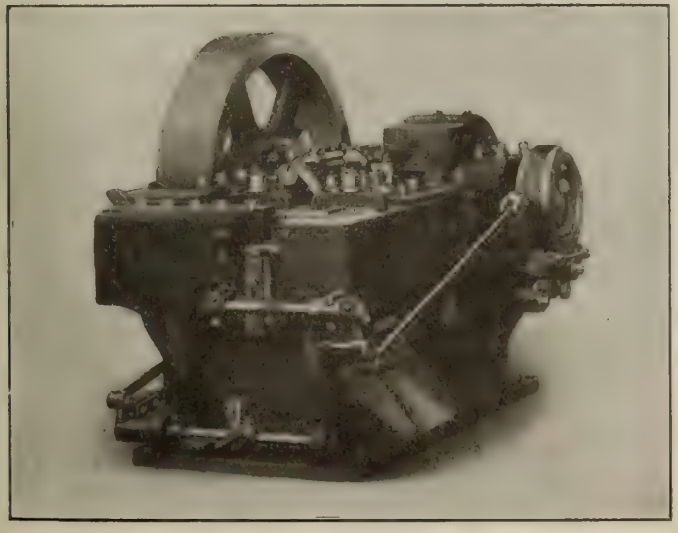


The body of the machine is a single piece steel casting, with piston and valve cylinders cast integral, a method of construction which ensures perfect alignment of working parts. Large hand holes conveniently placed, facilitate access to all working parts for adjustment and lubrication.

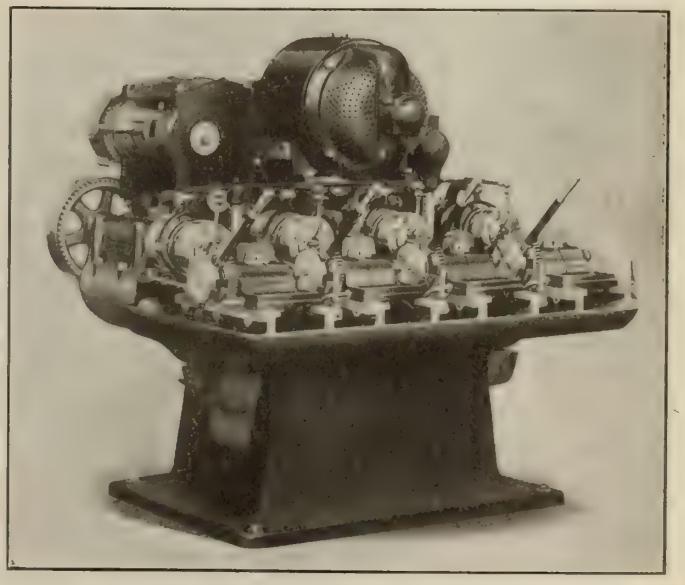
A NEW BOLT HEADER.

THE National Machinery Co., Tiffin, Ohio, are makers of the National Wedge Grip Bolt Header, which we here illustrate. It is claimed that the wedge gripping mechanism ensures long life to the dies, and causes a minimum loss of time for die changing and re-dressing. The grip relief is automatic, being another feature which makes for continuity of operation. The friction slip flywheel is also a noteworthy feature. If cold or excess metal stalls the machine, and prevents the heading tool from completing its full stroke, this friction-slip flywheel relieves the machine by dissipating its momentum through the slipping action, instead of throwing the entire strain on the shaft, bearings and machine generally. The motor is, of course, also protected by this equipment.

MOTOR DRIVEN QUADRUPLE BOLT CUTTER.



Another machine built by the National Machinery Co. is the quadruple bolt



The National friction-slip fly wheel.

cutter, driven by a standard type constant speed motor, either A.C. or D.C.

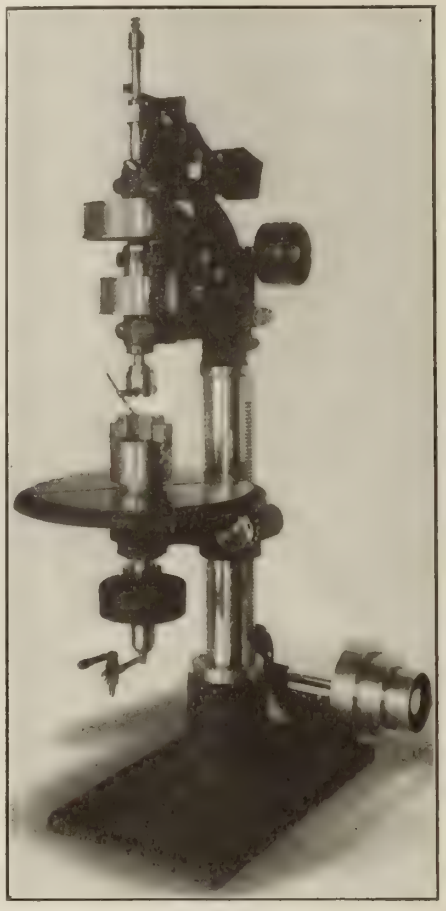
The motor does not overhang, therefore a minimum of floor space is occu-

The National wedge grip bolt header.

Motor-driven quadruple bolt header.

pied. When desired, the spindles can be run independently, and there is a patented speed change device, which gives four speeds by direct gearing. The dies are held in interchangeable cases, and have a long cutting face, allowing more sharpenings than usual with hob-bed threading dies. The machine is quite rigid, and will cut an accurate thread under all conditions of diameter variation, or hardness of stock cut.

DIE SHARPENER.



The National Machinery Co., also make the die sharpener, illustrated. This grinder is rapid in operation, and is claimed to equal the work of four men on hand grinding. It is designed to secure the correct throat or entrance, with proper clearance on each die, and grinds all dies in a set to equal depth, so that each will do its full share of cutting. This accuracy makes for the highest posible die service, prolongs their life, and results in a better qualty thread.

GARVIN NO. 2A AUTOMATIC TAPPING MACHINE.

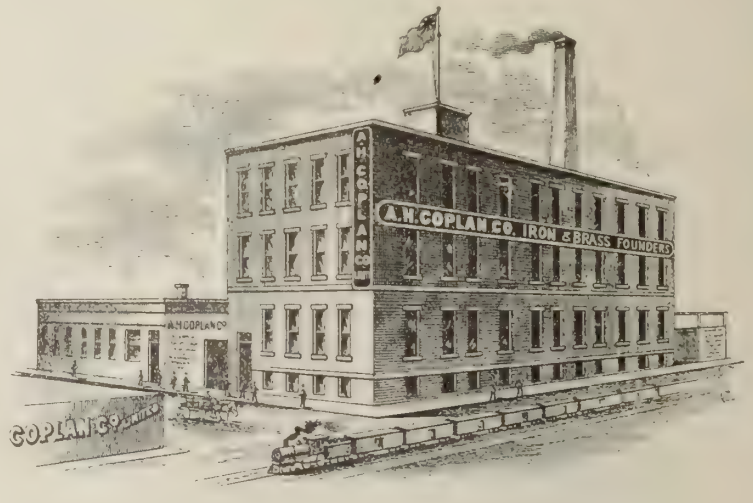
THE Garvin Machine Co., New York City have added two more automatic tapping machines to their line, one of which is an extra capacity, to their present No. 2. This new machine will operate from $\frac{1}{4}$ to $\frac{7}{8}$ inch U.S.S. taps in cast iron, from $\frac{1}{4}$ to $\frac{3}{4}$ inch in steel, for $\frac{1}{2}$ inch pipe taps in cast iron, and $\frac{3}{8}$ inch pipe taps in steel.

The other machine, No. 2 back geared, has a capacity from $\frac{1}{2}$ to $1\frac{1}{4}$ inches in cast iron, $\frac{1}{2}$ to 1 inch in steel, for $\frac{3}{4}$ inch pipe taps in cast iron, and $\frac{1}{2}$ inch pipe taps in steel. The machine illustrated, is the No. 2 extra capacity, equipped with a special chucking arrangement mounted on the table, consisting of a Garvin automatic wrenchless two-jaw chuck, operated by compressed air. This feature adds greatly to the productive capacity, as no time is lost in clamping and unclamping the parts being operated. A turn of the air-valve, opens the chuck jaws instantly, while a turn of the valve in the opposite direction, causes the jaws to grip the work securely, and ready for the tap. This is started for a couple of threads, by the hand lever, no further attention being required. The tap goes to the bottom of the hole, trips off, and returns automatically.

The spindle is fitted with two friction pulleys, driven in opposite directions by one continuous belt, and between these pulleys is placed a friction clutch, keyed to the spindle. The friction clutch is connected with a lever at the right, by a toggle arrangement, and adjustable for the desired tension, so that an extra safety device to prevent breaking of taps becomes unnecessary. The tap is started by the lever at the right, and tripped and reversed automatically, at

Garvin No. 2A Automatic Tapping Machine.

any point by an adjustable screw stop on the upper end of the spindle, striking the tripping lever on the top of the machine.



The spindle is balanced, and fitted with a positive drive chuck for holding the taps. The table is surrounded by an oil-groove, and is adjustable up and down on the column to suit the work.

The valuable feature of this tool, is that it operates satisfactorily at high speeds, and will trip and reverse after being set, though the operator should continue to press down on the starting lever.

THE A. H. COPLAN CO., LIMITED, OTTAWA, ONT.

The A. H. Coplan Co., Ottawa, Ont., have recently enlarged their works with a view to carrying on more extensively their brass and white iron foundry business. In addition to increased warehouse capacity, the brass foundry has been enlarged and equipped with the latest in oil melting furnaces by Francis Hyde & Co., Montreal. Pending the erection of their new iron foundry, the company have leased another foundry, with which to supplement their output, and keep pace with the orders being daily received and on hand. The dimensions of the present completed extension are 99 by 33 feet, and the accompanying cut gives some general idea meantime, of the plant as a whole.

The brand of white iron manufactured has established a reputation for itself at the Canada Cement Co. mills, and while embodying the useful features of semi-steel and malleable cast iron, it is, lower in cost. Orders amounting to between four and five tons of various alloys of brass, phosphor-bronze, aluminum, etc., are at present being filled. The company has been in business for about nine years, and is at present employing some 75 men. Their metal patternmaking department is another prominent feature, one of the specialities being match plates; while in wood patternmaking, a general business is done.

Mr. A. H. Coplan, who is quite a young man, devotes close attention to the management of the various branches of what has now become an important and successful undertaking.

CANADIAN MACHINERY AND MANUFACTURING NEWS

A monthly newspaper devoted to machinery and manufacturing interests mechanical and electrical trades, the foundry, technical progress, construction and improvement, and to all users of power developed from steam, gas, electricity, compressed air and water in Canada.

Vol. VII. September, 1911 No. 9

SELF IMPROVEMENT.

BEFORE another issue of Canadian Machinery comes into the readers' hands, the season during which opportunity is given for self-improvement will have again come around. We are desirous of helping in this work, and in addition to the continuation drawing and sketching lesson every month, we purpose, with the co-operation of our readers, increasing the scope of that section of our paper devoted to "Methods and Devices."

It needs to be pointed out that contributions to that department are not expected to be strictly new creations. To many, perhaps, some or all of the ideas that appear from time to time are more or less familiar daily practice. While this is so, it should be realized that to the majority of our readers there is much that is absolutely new, and for which they look greedily, we might say each month. Men located in our large, well-equipped manufacturing and railroad machine shops, do not sufficiently realize how much they owe to the slow yet certain development of improved methods and devices by operators here and there among the general body of employes. They do not realize that small and medium size machine shops scattered all over this wide Dominion have in their employ men who are thirsting to know what the big fellows are doing and how they do them. Again, these employes of the large shops may learn much from the smaller, because, often as not, the very smallness and paucity of equipment demands ingenuity of the highest grade.

Reciprocity is in the air; as a matter of fact, it is all-pervading just at the moment, and while its adoption by Canada and the United States may or may not be a boon to either or both, there is no question as to its value between employes working in variously equipped plants. Canadian Machinery reaches the whole field, and provides the barter ground on which ideas are traded; therefore we suggest, as a truly instructive and educative programme that our readers set themselves ploddingly and enthusiastically to the task of contributing periodically brief articles covering some of the hundred and one "kinks" which ingenuity provides for the better production and quicker output of work under any circumstance. The time so spent will bring its sure and natural reward.

1911 CANADIAN NATIONAL EXHIBITION.

THE Canadian National Exhibition at Toronto is now in full swing, and judging from impressions formed of the opening days' achievements, it bids fair to eclipse all previous records. The machinery hall, in which, of course, are or should be found exhibits worthy of Canada's development in the mechanical field, is filled to the "crowding-out" point, yet numerous firms who should be showing their manufactures, are not in evidence.

We unhesitatingly affirm that due regard is not being paid to the requirements of those whose product belongs to this section, and while report has it that a remedy will be provided by increased and more specialized accommodation in another year, no time should be lost in giving absolute confirmation, if such be the intention, and in getting details into shape. Machinery manufacturers, we know, desire this opportunity of displaying their product, but for the most part are handicapped by the want of a setting through which it will be given justice. Modern factory design and layout is in many cases infinitely superior for the display of the finished machine than the present exhibition hall, therefore, it is only natural that much material is withheld on that account.

Machinery enters so largely into the opening up of our country and interests so large a proportion of its population that no valid excuse exists for its longer occupying so insignificant a department in Canada's National and Annual Exhibition.

LABOR DAY.

THE Festival Day of Labor falls to be celebrated in the Dominion of Canada on Monday, September 4th, and the bearing of some part in its fitting recognition is more or less incumbent on all. Most of us are born with the heritage which calls to labor, therefore we can and should join heartily in the enjoyment of a day when work is laid aside in favor of the pleasure which its rewards bring.

Labor Day as an institution is growing in favor, that finely drawn distinction which sought to confine its scope and ignore its universality of application, being clearly in process of complete disappearance. We believe that this new attitude inspires increased reasonableness and conciliatory measures to assert themselves on occasions of trade and business troubles.

These latter are bound to appear periodically, arising as they do to a large extent, from civil, educative and industrial progress, and our main concern should be not only a smoothing of the transition process, but a promulgation of such schemes and methods as will easily and quickly dissipate friction.

FOUNDRY PRACTICE AND EQUIPMENT

Practical Articles for Canadian Foundrymen and Pattern Makers, and News of Foundrymen's and Allied Associations. Contributions Invited.

CHEMISTRY IN THE FOUNDRY.

By S. B. Chadsey, Toronto.

IT would appear almost unnecessary to discuss this well-known subject, the theme of so many articles in the technical press during the last 10 years, were it not for the fact that there are still many foundrymen who underestimate, just as there are perhaps a few who overestimate, the value of the service that chemistry has rendered and is rendering to their industry.

Those who underestimate its value include the many who have never given it a trial, and some few of those who have. Of these two classes, the latter are the most difficult to persuade.

Foundry Chemistry Failures.

Foundrymen are to be met with who claim to have made the attempt to avail themselves of chemical methods, and which to them have produced negative or disastrous results. That is to say, they have either found no especial benefit accruing, or have encountered serious losses as a consequence. In cases of this nature that have come under the writer's personal observation, the failure has been invariably due to some misconception on the part of the chemist. Some have merely failed to observe any perchance benefit, others have made only a brief trial, and others again have had an analysis of their material made at infrequent and irregular intervals, but having no very clear idea of the significance of the results submitted to them, simply passed these over, with but slight attention.

Such courses of action and methods invariably fail, whatever the object of their application, therefore, further comment is needless.

Causes of Chemistry Failures.

Cases of positive and perhaps serious loss, due to chemistry, so called, are usually, if not always, caused by failure to realize that chemistry is only an aid to efficient foundry management, and that it can only be of value when used by someone who is thoroughly conversant with good foundry practice. Instances are undoubtedly on record where inexperienced analysts have been called upon to take charge of foundry operations for which they were not prepared, and these have frequently produced disastrous results. In all such circumstances, however, the fault has been chargeable to the management, whose failure to appreciate the true value of things, began with an exaggerated opinion of scientific methods, and ended in their wholesale condemnation. Neither position is the correct one. In a recent publication by Edward Kirk, it is somewhat surprising to find statements such as the following: — "About the year 1900 the American and various local foundrymen's associations took the matter up, and every opportunity was afforded chemists to make foundry chemistry a success. That the results obtained from these opportunities afforded, have been a disappointment to the founder is undisputed, for castings, made from anthracite and coke smelted iron, possess no greater transverse or tensile strength than those made before chemistry was introduced; and work is cast with no more certainty as to hardness, softness or strength of casting than was formerly done by fracture indications." — "The writer's attention was recently called to a mixture made by a practical foundry chemist in charge of a foundry. These five ingredients, silicon, sulphur, phosphorus, manganese and carbon, were determined, and a mixture made by analysis for soft castings, yet all of the latter were found too hard to be machined. Investigation showed that a new brand of iron placed in the mixture contained titanium in sufficient quantity to harden the whole combination."

S. B. CHADSEY

Canadian Representative, American Foundrymens' Association.

These statements are entirely misleading, and it is unfortunate that they should be made, evidently on insufficient data, by one whose name carries some weight with many foundrymen.

Practical Services of Chemistry.

In commenting upon them, we desire merely to express the main practical daily services of chemistry to the modern foundry. They are, we believe, as follows.

I.—The definite and certain regulation of foundry irons, so that the metal for every cast, shall be of the desired grade. It is readily possible, to produce at every cast, iron required for the work on hand, if suitable raw materials are provided and the melting practice is good. If soft iron is required, there is no reason why soft iron of a particular grade should not be always forthcoming. Such regularity, however, can only be secured through the agency of chemical analysis.

II.—The investigation of the details of melting practice, all of which are dependent upon chemical laws.

III.—The additional aid afforded by chemistry, in determining the causes of variable conditions, wherever they occur in connection with the casting process, and the greater consequent facility, with which conditions may be standardized.

To attain these results, it is necessary that chemical work should be regularly and systematically pursued, and through either private or commercial laboratories, this privilege and advantage is made available to practically every foundry, whatever its capacity or value of output.

DEFECTS IN SMALL CASTINGS.

By John H. Eastham, Montreal .

Those castings which make the average foundryman grey-headed before his time, do not usually weigh several tons each, but are rather those of the small variety, ordered in large quantities, and in many cases of the plainest design. The writer, in quoting a case in point, may therefore, perhaps be pardoned for treating the somewhat hackneyed subjects of proper gating and venting.

An English firm of cotton machinery makers required several thousands of small collars or bushes annually, of type shown in sketches of pattern plate, Figs. 1 and 2. These collars were of various sizes, the heaviest weighing about 8 pounds. They were polished absolutely clean and bright, and were in all cases mounted on cast iron pattern plates, about $\frac{3}{8}$ inch thick. The boxes employed were 18 by 12 inches, provided with a guide pin at each end, one round and one square, to avoid mistakes in closing, when in use on ordinary hand rammed turnover machines. A wedge

driven in at each end, between pin and cope part, sufficed to hold down the molds when cast. The facing sand used for small work in this particular foundry, was ground fine in a heavy mill to facilitate drawing patterns, and secure

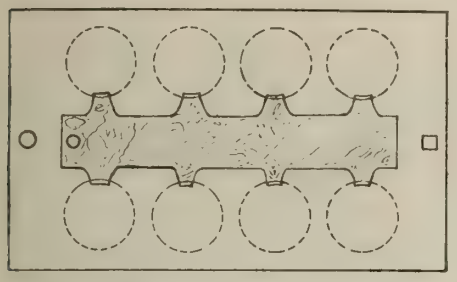

Fig. 1.—Defects in Small Castings.

perfect lifts, in most cases without the aid of gaggers. The collars in question, when first mounted on pattern plates, were gated in the drag part, an ordinary spray runner being fixed to the under side of plate.

Faulty Castings and Their Remedy.

For some time, the number of faulty castings discovered in the lathe, was quite 15 per cent. Changes of mixture, hotter metal, and careful skimming having no effect, the foreman decided to try a heavy runner, of type shown in sketches, fixed to the cope side of the plate, the sprays overlapping each casting about $\frac{1}{8}$ of an inch. This had the effect of removing the sponginess and dirt previously encountered, but a new disease developed, in the shape of minute blowholes around the top of each casting.

Free use of the vent wire and of ordinary floor sand on face of cope parts being of no avail, the foreman came to the conclusion that gas from under the heavy runner found its point of least resistance in the molds just before each casting was quite full, and decided to attach strips of lead to the drag side of the plate between the castings, extending

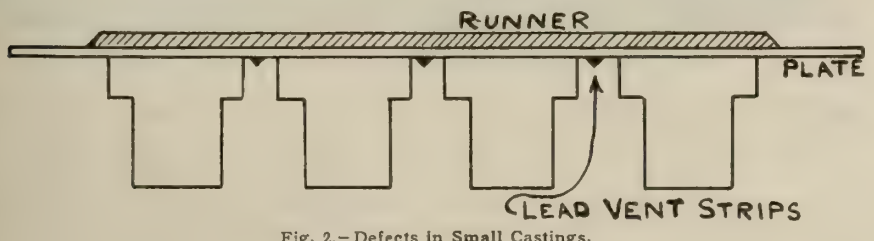

Fig. 2.—Defects in Small Castings.

almost from the top runner right to the box edge.

The loss was brought down to about one per cent., showing that the result justified the experiment. Since then, the vent wire has been ignored on this particular job, to the satisfaction of both molder and employer; all plate and machine jobs in the shop being rated on a piecework basis, a fair price being paid for good castings only.

TYPES of FOUNDRY CONSTRUCTION.

By George K. Hooper.*

I am somewhat opposed to reinforced concrete for foundry construction, on account of what might be termed, "manufacturing elasticity," because it does not adapt itself too well to the alterations and extensions which are constantly being made in plants devoted to foundry work. Brick, concrete blocks, and hollow tile are the most adaptable, brick probably being more so than any of the others, and considering the present price of brick, no saving can be effected by the use of the other two forms of covering, although in large foundries, the weights of steel can be maintained at the minimum, by the use of hollow tile above the windows.

While I have always furnished plans to reinforced concrete contractors, that they might compete with other forms of construction, I have not yet been able to secure a bid as low, or to have as cheap a building as that from other materials. When I say this, I give due appreciation to the question of insurance, locality and contents being considered by the underwriters, as well as the type of the building.

For interior partitions, hollow tile makes a firm, cheap wall. Concrete plaster on wire laths, expanded metal, or galvanized netting, usually requires so much supporting steel, that it is quite expensive, and practically costs more than tile, while not possessing the advantages of the latter. Steel roof trusses should be carefully designed so as to be conveniently reached with cleaning and paint brushes; this more especially in foundries of the continuous type, where considerable vapor arises from the cooling sand. The trusses and columns should be carefully and thoroughly painted.

Windows, except where there is an exposure, are generally made with wooden frames, glazed with factory ribbed glass, and should be fitted to tilt, in order to secure the greatest possible opening. There was at one time, a craze for making walls almost entirely of glass and steel. Such buildings, however, are difficult to heat in winter and to ventilate in summer, while the glare of the direct sunlight is most unpleasant. Many plants of this kind have adjusted curtains to the windows, or painted over portions of them and in some cases large sections of glass have been removed. A building wall containing 50 per cent. of window space, will usually be very completely lighted for any width of structure, and in any event, passages and storage departments can be placed in the darker sections.

I am an advocate of metallic bars and ribbed glass for skylights, and in continuous foundries where a large amount of vapor is present, a copper bar is cheapest in the end.

*The Hooper-Falkenau Engineering Co., New York.

THE DETROIT CORE MACHINE.

The illustrations, Figs. 1 and 2, represent the Detroit Core Machine jar-ramming and rolling-over a large core by means of a clamp held with one hand respectively. The core room, of all departments in the foundry has been most neglected, and why this should be so, we are at a loss to understand. Money

Fig. 2.—The Detroit Core Machine, Rolling Over a Large Core.

may be and is lost there just as surely as in other sections, and a jar-rammed core has everything to recommend it as against one which is hand rammed.

A smooth uniform core is assured, eliminating hard and soft spots which often as not result in blowing and rough castings. A feature of this Detroit core machine is the fact that the core-maker works right at his bench, and stands right in his tracks to make his core, thereby saving much time and labor running around. The machine occupies small space, a consideration always of importance, and particularly if the core-room is crowded. The core box is easily drawn by means of the foot power device, giving a firm steady motion and obviating patching.

Fig. 2 represents a coremaker rolling-over a box with one hand, which on the bench would require two men to roll over. The box in question is 26 inches long, 16 inches wide, and 6 inches deep. The machine is equally adaptable for handling several small jobs at one time, and in this feature, its attractiveness as

Fig. 1.—The Detroit Core Machine, Jar Ramming a Large Core.

a time and labor saver is perhaps more apparent, because any number of cores up to its capacity may be negotiated in the time that one usually takes otherwise. The makers are the Detroit Core Machine Co., Detroit, Mich.

A GRAVITY CARRIER.

THE Canadian Mathews Gravity Carrier Company, 312 Stair Building, Toronto, incorporated with a capital stock of $100,000, has opened a factory at 28 Sheppard street, Toronto. The company holds numerous patents covering ball-bearing gravity carriers, spiral chutes, automatic elevators, etc. Gravity carrier systems have a wide range of usefulness as applied to the handling of such merchandise, as brewery cases, boxed goods, shingles, lumber, barrels, cooperage stock, pig iron, and other commodities, having one or more flat surfaces, which allow them to move forward of their own weight, on a carrier line adjusted to a slight grade

This carrier was introduced by the Mathews Gravity Carrier Co., St. Paul, Minn., about six years ago, and has been highly successful.

The officers of the Canadian company are:—H. L. Jenkins, president, Vancouver, B.C.; F. E. Moore, vice-president; O. C. Sylvester, treasurer and managing director.

The half tone shows the gravity carrier in use, unloading cooperage stock from a box car. The rollers consist of seamless steel tubing, running on two ball bearings. A straight line and portion of a curve is also shown. The latter being reversible, to permit of stock delivery in either direction. The straight line portions are made up in standard lengths of 8 feet, one of which may be seen against the side of the car.

The Mathews gravity carrier.

MECHANICAL DRAWING AND SKETCHING FOR MACHINISTS.*

By B. P.

IN our last lesson, we showed how one view of an object is obtained from another by straight line projection. We will now apply the principle, in drawing the three views of a common hexagon nut. Drawing a hexagon nut, involves the use of a 60 degree set square, and when the student can draw a hexagon with one of its points at any angle, in relation to vertical or horizontal centre line, he will realise more fully than many a column description would teach him, the numerous uses to which set squares can be put.

Drawing a Hexagon Nut.

A hexagon nut is frequently made of the following proportions, If we call the diameter of the bolt, D, the nut will have a width across the flats of $1\frac{1}{2}$ D + $\frac{1}{8}$ inch, and a height equal to D. Thus a nut for an $1\frac{1}{4}$ inch bolt will be $1\frac{1}{4}$ plus $\frac{5}{8}$ plus $\frac{1}{8}$, or two inches across the flats, and $1\frac{1}{4}$ inches high.

Fig. 1 shows how to draw such a nut. Commencing with the plan view, draw two centre lines at right angles to each other. With their point of intersection as centre, describe a circle whose ra-

*Seventh of a series of an instruction course.

dius will equal half the diameter of the bolt, or $\frac{5}{8}$ inch. Next describe from the same centre, a circle equal to the width of the nut across the flats. In this case the width is 2 inches, therefore the compasses are set to a radius of 1 inch.

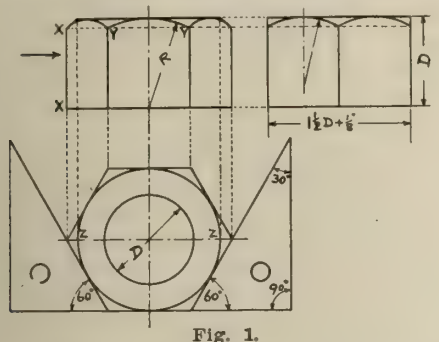

Fig. 1.

Now, take the 60 degree set square as shown, and draw lines tangent to this circle on each side, turn the set square over and draw two others. This gives four sides of the nut, the remaining two being got with the tee square. From this plan, the elevation above it, (which shows the nut from corner to corner), will be projected. Four corners, and three faces of the nut are seen, the middle face only being true width. The other two appear narrower, because they are inclined at 60 degrees to the vertical plane, on which the elevation is projected. The view to the right hand is in the direction of the arrow, and shows three lines, that in the centre being for the edge XX. The other two lines are the outer faces, their distance on either side of the centre line, being measured from the plan view.

The 2 inch circle in the plan shows that the corners are turned-off or "chamfered," the upper views showing that this turning-off is at an angle with the centre line. In the elevation, this is shown by the line YY, drawn from the centre of the bottom of the nut with a radius R, equal to its thickness, or in this case $1\frac{1}{4}$ inches. This face shows the true form of the curve, while the two others, being inclined, appear as small portions of an ellipse. Since they differ very little, however, from true arcs of circles they are in practice always drawn as such.

The nut is flat on the top from Z to Z, (see plan), and the figure shows how these points are projected up to the elevation, and a line drawn tangent to the arcs on each side. The end view presents no difficulties, its construction being clearly indicated.

Methods of Using Set Squares.

Fig. 2 shows the method of drawing a hexagon with one corner at various angles with the horizontal, and forms a good exercise in the use of set squares. The figure also shows how to construct an angle of 15 degrees. The student should draw these exercises until thoroughly familiar with the method employed, as the necessity for their application constantly occurs.

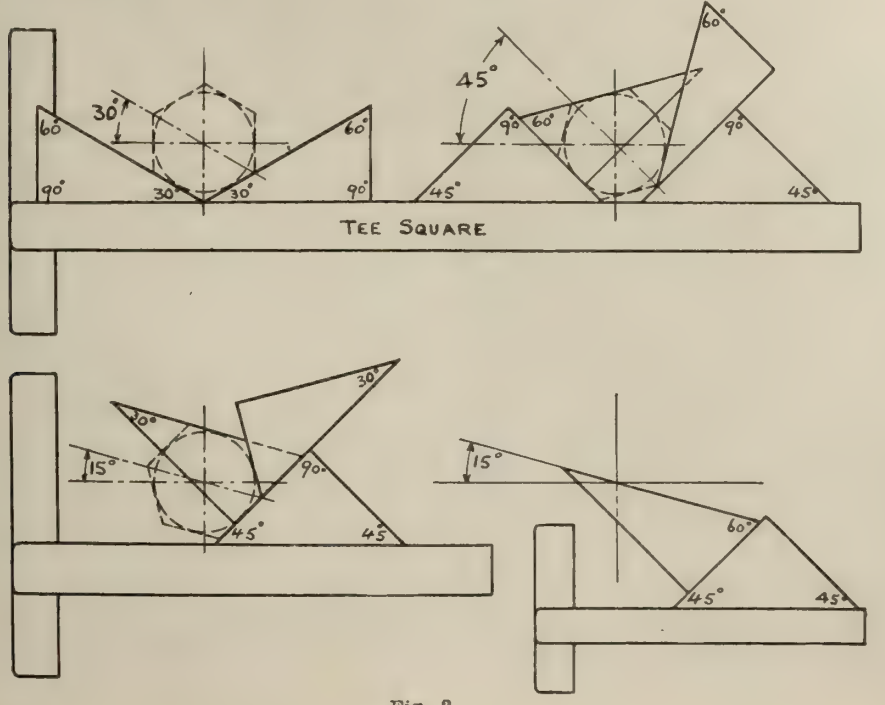

Fig. 2.

Practical Examples.

Fig. 3 shows good proportions for an ordinary spanner. The thickness and breadth of the shank are shown expressed in terms of the width of the nut A; but these are not necessarily rigidly adhered to. For instance, if A is 1 1-16 inch, we will find that $\frac{5}{8}$ A plus $\frac{3}{8}$ inch, works out to about 1 1-32 inch. This in actual practice would be made 1 inch or 1 1-16 inches. The thickness of the head of the spanner is usually made equal to D, the diameter of the bolt.

In making the drawing, we first construct a hexagon in light dotted lines to represent the nut, this can afterwards be erased, if desired. Through the back, top and bottom corners of the hexagon drop a vertical dotted line as shown. This line will cut the circle which touches the sides of the nut at two points B and C. Join the centre of the nut O to each of the points B, C, and continue the lines to D and E. Set the needle point of the compass at B, and the pencil point at the top outer corner of the nut; this radius is shown as r in figure 3. With B as centre and r as radius, describe an arc from the top outer corner of the nut, as far as the line O B D —the point D being where the two lines intersect. Repeat this operation from C as a centre.

Next set the needle point of compasses at O, and pencil point at D. With this radius, shown in the figure as R, join up the two arcs already drawn.

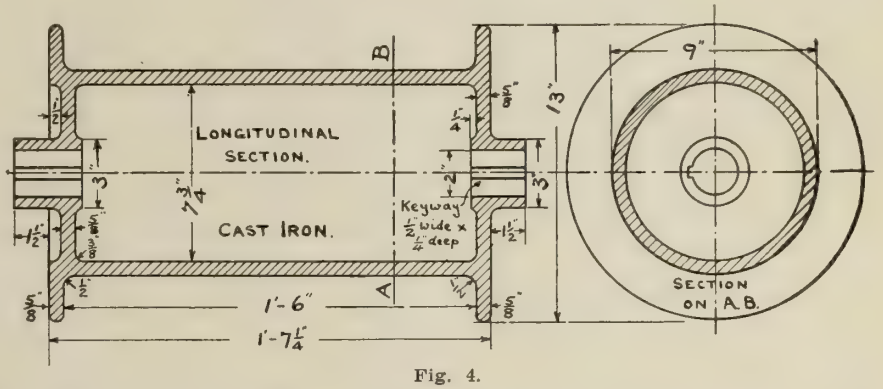

Fig. 4.

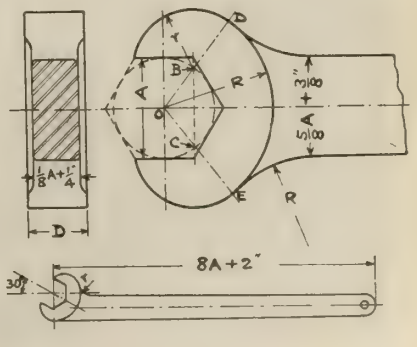

Fig. 3.

SYSTEMATIC BUSINESS MANAGEMENT

Practical Articles for Managers, Superintendents, and Foremen, to Assist in Carrying on the Business Economically and Efficiently.

The Artificial Lighting of a Factory Location

This Article Goes to Show the Benefits Derivable From a Well-lighted Machine Shop, With Respect to Quality and Quantity of Output, the Spirit and Enthusiasm of the Men, and the Possibility of Accomplishing These Results on an Early Repayable Outlay, at Minimum Operating Cost of Renewals, Under Circumstances Where Vibration is of Sufficient Importance to be Accounted.

By E. R. Treverton.

AMONG the reports on lighting installations, that have appeared in the past months, comparatively few deal with the question of lighting the rougher locations, such as machine shops, mills, factories and the like, due to the fact, no doubt, that little has been done along this line, or that those conducting the work, have little time to report on it. It is the object of this article, to describe how a very dark machine shop was lighted by a simple, but effective method, which gave entire satisfaction to all concerned.

Machine Shop Description.

The location in question is a typical inside factory one, consisting of an aisle 40 feet wide, situated between two other aisles of slightly greater width, and separated from them only by the columns that carry the roof. Four hundred feet of this aisle is used for general machine (mostly lathe) work. The ceiling 12 feet high formed by the 2 x 8 inch wood floor above, is divided into 40 x 16 feet bays, by the supporting girders. A crane runs the entire length of the aisle, with a clearance of only 13 inches above the hoist. The natural lighting comes from the aisles on each side, one of these having a row of windows occupying the entire outside wall, the other making use of sky lights and a row of windows just under the roof, at a height of about 50 feet from the floor. The light from the first source was mostly cut off, by a row of high machines directly in front of the windows, and by the intervening columns, crane girders, and the like. From the other side, the windows being so high in comparison with the width of the room, only a narrow strip of the floor was directly lighted, and this imperfectly, on account of the machines located just along the edge of the aisle. It was necessary to use artificial light at all times, as under the best conditions of a bright day, the natural light was exceedingly dim, and presented a worse condition than if there had been absolute darkness, because the mixture of daylight necessitated a higher artificial intensity than would otherwise have been necessary.

The Lighting Problem Solution.

Formerly, clusters of carbon lamps scattered here and there, formed the general lighting scheme, each machine being furnished with one or more extension lamps, which were moved from place to place as the operator required. Not only was the light insufficient, but the continual transfer of lamps, with their consequent breakage and cord damage, made the maintenance cost so high, and reduced the efficiency of the workman to such an extent, in quality and quantity, that a change became absolutely necessary. It was further impossible to keep good men, on account of the inconvenience and unpleasantness of their surroundings.

The small clearance over the crane, together with the low ceiling, excluded all types of lamps except the incandescent. Carbon lamps in sufficient numbers, would have required an excessive current consumption, therefore, tungsten units were selected as being the most applicable. There was, however, some doubt as to the advisability of adopting tungsten lamps, as the floor above was used for machining heavy castings, and the constant dropping of these, it was feared, would cause a large lamp breakage, because of their being of the old fuse type. To determine the exact effect on the life of the lamps, two bays were each equipped with 8—100 watt, clear tungsten lamps, having intensive glass reflecters mounted directly on the ceiling. One inch of free cord intervened between the rosette and the socket. The lamps were arranged in two rows of four lamps each, per bay, making the spacing distance 8 x 10 feet, and the power consumption 1.25 watts per square foot of floor space. The switching was arranged so that four lamps could be operated in a group, thus permitting small areas to be lighted without waste. After several weeks operation, the breakage was found to be small, and subsequent replacement by Westinghouse Wire-Type lamps caused it to disappear altogether regardless of vibration due to cranes, and dropping heavy weights on the floor above.

Lighting a Factory Location.

Operating Results Achieved.

The illumination was uniform and of sufficient intensity for the class of work done, and the shop was transformed from a gloomy, into a cheerful location. The spirit of the men improved, as was shown by the quality of the work turned out, the floor was kept cleaner, and the whole appearance of the place changed for the better. Further, the general results were deemed so satisfactory that the entire 25 bays were similarly equip-

ped, all extension lamps being removed, except where necessary to see into deep work or under machines. For these latter purposes, plug boxes have been placed at convenient places, and extension lines used only when necessary. The general lighting scheme is therefore, never interferred with, and the place is entirely free from the mass of cord that previously characterized it.

Duration Test.

The new system has been in service for well over a year, and careful records show the cost to be not only reasonable, but that saving in quality of work, and ability to keep good men, has more than repaid the original expense.

The accompanying photograph, taken at night without any light except from the ordinary source, shows the location and gives some idea of the satisfactory character of the illumination. All parts of the room are sufficiently lighted, to permit work being done with equal ease at any point. Tests showed that the average intensity on the horizontal plane was 2.5 foot-candles, with a minimum of 1.6 foot-candles at the extreme edge of the room.

THE HOLDEN-MORGAN CO., TORONTO.

The Holden-Morgan Co. have a well-equipped modern machine shop at 50 Pearl St., Toronto, and carry on a general machinist business, in addition to making cutting, blanking and forming dies, special experimental apparatus, etc. A. P. Holden, late of the Scholfield-Holden Machine Co. is president and general manager, while Philip Morgan is vice-president and superintendent. The latter was for twelve years mechanical superintendent at the Newmarket works of the Office Specialty Co., of Toronto.

The illustration shows a corner of the machine shop, where about 25 men are now employed, as against 8, some nine months ago, when the business started.

The equipment, all new, includes engine lathes, swinging from 14 to 24 inches, built by the American Tool Works Co. and fitted with quick change speed gears; Kearney and Trecker Co.'s milling machines, both plain and universal; Becker vertical milling machine; 16 and 24 inch; McGregor-Gourlay shapers; Le Blond cutter grinder, and various miscellaneous tools, including drill presses, speed lathes, power presses, arbor presses, etc.

The shop is noticeably clean; the floor and benches are of hard wood, and dirt in every form is vigorously chased. The men are supplied with "screw-jack" stools, which have hard wood tops and cast iron bases. The work benches are lighted on the Almond system, flexible metallic tubing allowing adjustment of the lamps in any direction. The operators of the principal machines are provided with convenient stands, mounted on castors. These were made in the shop, and consist of two shelves and a drawer about two feet square. They are mounted on a frame of wrought iron pipe, and form a convenient receptacle for small tools, milling cutters, jigs, etc. There is a No. 1 American gas oven and blower for hardening, and a blowpipe equipment for brazing.

Holden-Morgan Machine Shop.

The contracts on hand, include automatic candy wrapping machines, check book presses, automatic paper bag machines, sand papering machines, paper coating machines, as well as a number of automatic jigs, fixtures and small tools.

The company intend to purchase property in the near future on which to erect a larger and still more convenient factory.

"WELFARE" WORK.

The extent to which the United States Steel Corporation is carrying on "welfare" work in its mills, is shown by an official statement, that to date in the present year, there has been spent almost $700,000 for improving the conditions under which the workmen are employed. This sum has been expended on the installation of safety appliances, the establishment of cooling systems, especially in the sheet and tin plate mills, on the erection of hospitals, improving the labor conditions in the coke regions, and on undertakings of a similar character. Appropriations, totalling in the aggregate, the above sum, have been made for these purposes from time to time during the past seven months.

NOTES ON CONSTRUCTIONAL DETAILS.

Every machine or structure is designed with a certain object in view; therefore in designing, keep that object always to the front and let it influence every thought and action. Go straight to the point and let the object be attained in as simple and direct a manner as possible. It should be remembered that machines and other structures designed in this way, with the least material for the work to be done, usually look well and cannot be improved in appearance by outward embellishments.

Parts subject to stress should have as little change in form as possible, and if change is necessary it should not be of a sudden nature; these remarks especially refer to cast-iron, where a sudden angle or opening with square corners (even if not very sharp) may cause fracture when the section might be thought more than ample. Steel castings should be as simple and as free from ribs or brackets as possible. Ribs or nerves which run lengthways are not, however, as objectionable as those across the lines of principal contraction, but the soundest of metal under such projections is often doubtful, so that they may be a source of weakness instead of strength.

INDUSTRIAL AND CONSTRUCTION NEWS

Establishment or Enlargement of Factories, Mills, Power Plants, Etc.; Construction of Railways, Bridges, Etc.; Municipal Undertakings; Mining News.

FOUNDRY AND MACHINE SHOP.

FORT WILLIAM, ONT.—The stove works of W. J. Copp, Son & Co., Fort William, Ont., is being taken over by F. W. King, London, Ont., and others. The plant will be enlarged and overhauled.

HAMILTON, ONT.—Bowes-Jamieson, Ltd., Hamilton, Ont., formerly Bowes, Jamieson & Co., will enlarge its plant after the first of the year, and the capacity of the foundry will be increased from 7 to 10 tons per day. Molding machines will be installed along with other equipment.

HAMILTON, ONT.—The Hamilton Foundry was damaged to the extent of $1,000 by a fire which started near one of the core ovens and burned its way through the roof.

HESPELER, ONT.—The Hall, Zryd Co., of Grimsby, who recently purchased the idle plants of the Parkin Elevator Works and the Dominion Heating and Ventilating Co., from the corporation are now preparing plans for the building of an addition to the moulding shop of the former works. It will be 37x60 feet, and when completed, will give the company a moulding shop 60x85 feet, which will comprise but a part of the immense moulding shop to be completed next season.

TORONTO, ONT.—The National Cash Register Co., Dayton, Ohio, have taken an option on ten acres in the northern part of the city, and in the spring will erect a model factory. Their present factory on Lombard Street is entirely inadequate.

DAVIDSON, SASK.—Messrs. Allen, McNeil and Brown, woodworkers, machinists and blacksmiths, commenced business here recently.

RED DEER, ALTA.—J. W. Broughton, of the Red Deer Ironworks, is contemplating the establishment of a foundry in connection with his business.

HAMILTON, ONT.—The Schacht Motor Car Co., of Cincinnati, have decided to establish a $350,000 plant here.

INGERSOLL, ONT.—An industry which promises to be a large concern, is the Fruit Machinery Co., situated a little east of Thames St., on the C.P.R. This firm came to Ingersoll a few months ago from Western New York, where factories have been established for years. Their employees come from the same section and are experts. Fruit machinery of all kinds is manufactured and the only evaporating factory machines made in Canada are turned out by this firm.

MONTREAL, QUE.—The John McDougall Caledonian Iron Works have entered upon the manufacture of plunger elevators, passenger or freight. They will be built in the company's shops on Seigneurs Street.

STRATFORD, ONT.—The Macdonald Thresher Co., Limited, with head office at Stratford, is the name of the new company which has been formed to take over and carry on the business of the Macdonald Manufacturing Co., which for many years successfully conducted the manufacture and sale of separators, traction engines and other threshing machinery in Stratford.

VANCOUVER, B.C.—The largest single shipment of saws ever made to a Western Canada mill passed through here recently. The consignment consists of ten tons of circular and board saws for the lumber mill of the Ocean Falls Co. The saws and a large consignment of electrical machinery come from Hamilton, Ont.

SWIFT CURRENT, SASK.—W. H. Hodgson has about completed the construction of a garage and machine shop here. The former is 40x50 feet, the latter 30x32 feet.

CHILLIWACK, B.C.—Thos. L. Lillie has purchased the business known as the A. J. Robertson Machine Works.

EDSON, ALTA.—The Grand Trunk Pacific will establish car and machine shops here. They will be of standard capacity.

FORT WILLIAM, ONT.—The city has been asked to enter into a deal with Messrs. Kirkpatrick and King whereby the former will guarantee the bonds by which the Copp Foundry is to be taken over and enlarged by the new company. The matter will likely be referred to the ratepayers.

MONTREAL, QUE.—The Canadian Pacific Railway has started work on another huge undertaking in connection with their Montreal transportation facilities. Out near Western Junction the company is building a new terminal headquarters, which consists of a large twenty-four stall engine house, a machine shop, a turntable, a coaling plant, a stores building, a rooming and lodging house capable of accommodating one hundred men, and a car shunting and storage yard of two thousand cars capacity. Eventually the new terminal will have a capacity of four thousand cars.

PRINCE RUPERT, B.C.—L. B. de Laitte, the prominent French inventor, is establishing a plant here to manufacture gas machines.

MUNICIPAL.

MOOSE JAW, SASK.—One of the largest enterprises of the city this year is the sewerage system. Approximately $400,000 is being spent on it.

EDMONTON, ALTA.—It is proposed to erect a civic warehouse and stables for the city. The building will cost $10,000. There will be 46 stalls in the stables, besides four loose boxes, hay loft, caretaker's room and a cook room. The warehouse will be a three-storey structure, 70 by 100, while the workshop will be a two-storey building. The ground floor will be used for stores, water and electric light shop. There will be a carpenter shop on the second storey.

Trenton

On the main line Grand Trunk Railway, Canadian Northern Railway, Central Ontario Railway, Canadian Pacific Lake Shore proposed Railway and Trent Canal System. Water Shipment via Lake Ontario. Address

ARTHUR JONES,

Secretary Board of Trade, TRENTON, Ontario, Canada.

SARNIA, ONT.—The council has offered to buy out the Sarnia Gas and Electric Light Co. for $125,000.

HAMILTON, ONT.—Mr. Willis Chipman, the expert engaged to report on the waterworks system, has partly completed his report and given it to the Controllers. They have not made it public, but have stated that three of the principal recommendations made by Mr. Chipman have been anticipated. These are that a third electric pump be installed at the Beach, the placing of a new and longer intake into the lake, and the replacing of the high level pumping station with a new or improved plant. These works will cost about $115,000, and it is thought that the total waterworks improvements that may be necessary will cost about $500,000.

EDMONDS, BURNABY, B. C.—The Western Canada power by-law and the waterworks merger by-law were carried.

EDMONTON, ALTA.—The ratepayers defeated the by-law to grant a gas franchise to the International Heating and Lighting Co., Aby-law to provide for the establishment of a municipal gas plant will likely be submitted in the near future.

HIGH RIVER, ALTA.—On Sept. 5 the ratepayers will vote on a by-law to raise $125,000 for a waterworks and sewerage system.

TRENTON, ONT.—The ratepayers will on Sept. 5 vote on a by-law to raise $2,500 for sewers.

WEST LORNE, ONT.—The ratepayers defeated the waterworks by-law recently.

OAKVILLE, ONT.—The sewer by-law was carried by the voters.

SUDBURY, ONT.—The ratepayers carried by-laws totalling $146,000 recently.

MILTON, ONT.—The burgesses carried the by-law to extend the waterworks system.

CARDSTON, ALTA.—The ratepayers voted $40,000 for a gravity waterworks system.

SASKATOON, SASK.—The ratepayers passed by-laws totalling $95,000 recently.

CANORA, SASK.—By-laws totalling $91,000 for a town hall, waterworks and a sewerage system were carried.

KERRISDALE, B.C.—The ratepayers passed the by-law to spend $501,259.80 for waterworks extension.

NIAGARA FALLS, ONT.—The Muddy Run sewer by-law to raise $60,000 was defeated.

CALGARY, ALTA.—A by-law endorsing an expenditure of $20,000 for sewer purposes was carried.

CORNWALL, ONT.—The by-law to raise $30,000 for water mains was carried.

WINDSOR, ONT.—The by-law to expend $17,000 on on auto fire apparatus was defeated. The waterworks by-law for $50,000 was carried.

NANAIMO, B.C.—The ratepayers passed the $50,000 sewerage extension by-law and the B.C. Hydraulic Power Co. agreement.

STRATHCONA, ALTA.—The ratepayers recently passed the $100,000 Hospital by-law and the $10,000 new force main by-law.

MOOSE JAW, SASK.—On September 7 the city will pass on by-laws aggregating $166,000 for municipal improvements.

OTTAWA, ONT.—On Sept. 7, the voters will be asked to endorse an expenditure of $195,000 for waterworks.

GALT, ONT.—On Sept. 9 the ratepayers will vote on a by-law to expend $10,000 for waterworks purposes.

ELECTRICAL.

PRINCE RUPERT, B.C.—The work of making the surveys in connection with the plans of the Prince Rupert hydro-electric company has been going on here for some time. The programme recently adopted by the board of directors contemplates the expenditure of $600,000 during the next twelve months and $2,500,000 within the next four years. The company was recently incorporated with an authorized capital of $5,000,000. It represents a merger of the Tsimpsean Power and Light Company, and the Continental Power Company, owning exclusive water rights on the Kahtada river, forty-two miles from Prince Rupert, and at the Falls on the Exaw river, twenty-eight miles from the same city. English, French and Canadian capitalists are interested in the proposed enterprise.

The president is C. H. Cahan, K.C., of Montreal, president of the western Canada Power Co., which is developing Stave Lake Falls for supplying power to Vancouver and other points on the lower mainland. The general manager is R. F. Hayward, who occupies a similar position with the Western Canada Corporation.

5 Inch Capacity. 175 lbs net.

RIGIDITY

is the foundation principle for rapid accurate cutting, and this is provided in the machine illustrated. Note the depth of bed; also that the drive-shaft, guide, and saw blade are in the same line, securing a straight even pull that makes for **speed in cutting** and **economy in blades.** Machine is automatic and rings the gong when thru. Built and finished as a first-class machine tool to withstand the racket of continuous service.

Our 1911 Catalogue of valuable information regarding

"CUSHMAN CHUCKS"

is now ready. Better write for it. It's free on request.

The Cushman Chuck Co.
Hartford, Conn., U.S.A.
Established 1862

TORONTO, ONT.—Although the filtration plant is not yet finished the controllers are planning to enlarge it, and on Jan. 1, the ratepayers will probably be asked to say whether or not, seven more filter beds will be added at a cost of $420,000.

FOSTER, QUE.—The Brome Lake Electric Light Co. are making some extensive improvements to their plant here.

VERMILION, ALTA.—The town will expend $15,000 for a municipal electric light plant.

GRIMSBY, ONT.—On Sept. 5 the ratepayers will vote on a by-law to grant a loan of $10,000 to the Radiant Electric Co.

DAVIDSON, SASK.—The ratepayers will vote on a by-law to expend $10,000 for power purposes.

INDIAN HEAD, ALTA.—The ratepayers will, on Sept. 8, vote on a by-law to provide $25,000 for extending waterworks, sewers and electric light systems.

MIMICO, ONT.—The ratepayers will vote on a by-law to expend $7,500 for a power plant. Voting will take place Sept. 16.

HAMILTON, ONT.—A by-law providing $505,160 for a municipal power plant carried recently.

NAPANEE, ONT.—The by-law authorizing the town to sell the municipal electric power plant to the Seymour Electric Co. for $40,000 was carried.

INGERSOLL, ONT.—$25,000 will be spent on improvements to the electric light plant here.

PORT STANLEY, ONT.—A by-law was passed whereby the town will purchase Mitchell's electric light plant and install a Hydro-Electric power and light plant.

MIDDLETON, N.S.—The contract to install the electric light plant here was given to the Canadian General Electric Co. for $4,000. The machinery is to be delivered within 60 days and it is expected that the system will be complete early in October.

St. LAMBERT, QUE.—The town council is taking steps to extend the electric lighting plant.

GENERAL MANUFACTURING.

MONTREAL, QUE.—The Sultana Mfg. Co. recently took out a permit for a $20,000 fireproof factory.

PORT ARTHUR, ONT.—Mr. Anderson is Contemplating the establishment of a factory here to manufacture wash tubs.

NEW WESTMINSTER, B.C.—The Tacoma Match Co., of Tacoma, will probably establish a factory here.

ALLISTON, ONT.—Defriez & Woodman, manufacturers of high-class jewelry and silverware, will establish a factory here probably about the first of the year. The firm is an amalgamation of three Toronto concerns.

GUELPH, ONT.—The Aspinwall Manufacturing Co., of Jackson, Mich., are taking steps to double the capacity of their plant here. They manufacture farm implements.

SARNIA, ONT.—Geo. S. Tillotson, treas. and manager of the Sterling Emery Wheel Mfg. Co., of Tiffin, Ohio, was in town recently. He is contemplating the establishment of a branch factory here.

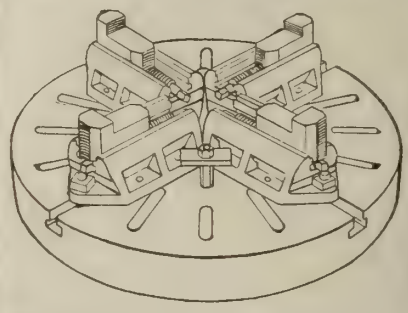
BUILDING NOTES.

SASKATOON, SASK.—G. A. Martin will erect a three-storey temperance hotel here at a cost of $70,000. The building will contain 140 bedrooms with bath, etc., in each.

VANCOUVER, B.C.—S. Jones will add six storeys to his two-storey building at the corner of Hastings and Hosmer Streets. The estimated cost is $125,000.

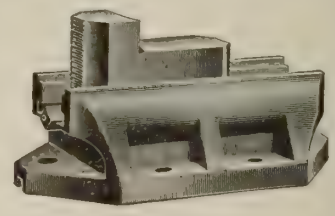
WINNIPEG, MAN.—Sveral large building permits were issued here recently, one to the Swift Canadian Co. for a wholesale market to cost $58,000 and a new refrigerator building to cost $30,000, and the other to the Sterling Bank for an up-to-date building. Swift and Co.'s buildings will be thoroughly equipped with refrigerators and cooling apparatus.

CANORA, SASK.—Jno. Limolt will make extensive additions to his hotel here. The entire building will be electric lighted, steam heated and modernized by a system of fire protection. The proprietor is installing his own electric light and waterworks plant.



TORONTO, ONT.—Mark Bredin, general manager of the newly formed Canada Bread Co., says that it is the intention of the company to immediately proceed in the erection of a modern bread plant in Winnipeg. He also intimated that the company would devote particular attention to the western field with great probability of it having plants in Regina, Calgary and Vancouver.

PRINCE RUPERT, B.C.—Work has been commenced on the $250,000 storage plant for Wallace & Co., canners, at Claxton on the Skeena River.



SASKATOON, SASK.—W. B. Sherman, theatrical manager of the Sherman enterprises, is preparing to erect a $100,000 playhouse here.

Jesse M. Warren, architect, recently prepared plans for an $85,000 building for a company of local men. It will be a four-storey fireproof and of reinforced concrete.

A Radial Drill

that will by foot power drill holes up to one inch without a pilot hole, at the speed of an inch in six minutes; with the slotted wings for awkward work; inexpensive, but one of the most useful tools ever designed.

This tool is the only really effectual foot drill on the market.

A tool that will earn its cost many times over. :: :: ::

Surface of Table Top,	23″ x 12″	Sensitive movement,	4¼″
Surface of Wings, -	23″ x 10″	Radial movement of arm,	120°
Travel of head on arm,	18″	Height over all -	5′ 10″
Arm will rise and fall,	6″	Weight - -	720 lbs.

SAW AND PLANING MILLS.

LADNER, B.C.—A new saw mill, near East Delta, operated by its proprietor, Mr. Moner, has started work. It has a cutting capacity of 40,000 feet per day. A planing plant is also being added.

VANCOUVER, B.C.—An electrically-driven saw mill and a box and door factory, representing an expenditure of $500,000 exclusive of the site, will be erected at the upper end of Lulu Island, by the British-Canadian Lumber Corporation. The driving of piles has just started and it is expected that the mill will be ready by January 1. 300 men will be employed.

FENELON FALLS, ONT.—A disastrous fire occurred here recently when Thomas and Connell's saw mill was wiped out by fire. A large shingle mill was also destroyed.

MERRITT, B.C.—Fire did $175,000 damage to the Taylor mill here recently. The entire plant, holds and 2,000,000 feet of lumber were destroyed.

VICTORIA, B.C.—The Canadian Puget Sound Lumber Co. have let a contract for $25,000 refuse burner to the Muskegon Boiler Works at Muskegon, Mich.

CONTRACTS AWARDED.

HAMILTON, ONT.—Messrs. David Dick & Sons, of Welland, Ont., have secured the construction work in connction with an addition to be made to the plant of The International Harvester Co. The structure will be of reinforced concrete, and cost approximately $250,000.

GUELPH, ONT.—The construction work in connection with a factory for the Independent Fire Co., has been awarded to Messrs. P. H. Secord & Sons, of Brantford. The amount is reported to be $47,000.

MONTREAL, P.Q.—The tender of the Northern Electric Co. to install a police alarm system throughout Westmount was accepted at $9,000 by the municipal council.

The Dominion Bridge Co. will do the steel work on the new fire station which amounts to $4,420, and the tender was accepted of Martin J. Quigley for plumbing on the station, amounting to $1,080.

NAME CHANGED AND PLANT ENLARGED.

The firm name of Bowes, Jamieson & Co., Hamilton, Ont., Can., manufacturers of stoves and ranges, has been changed to Bowes-Jamieson, Ltd. J. R. and J. W. Jamieson, sons of the former proprietor, will have charge of the active management of the business. The company is capitalized at $100,000. Shortly after the first of the year the company will enlarge its plant, the general arrangement of the foundry will be changed and the tonnage will be increased from 4 to 20 tons per day. Molding machines will be installed and some work will be mounted on match-plates. The company is in the market for a set of patterns of a medium-priced line of warm air furnaces.

ELECTRICAL STREET CONCRETE MIXERS

Something new in the line of street concrete mixers has been recently adopted by the city of Montreal. The unique feature of the 4 new machines which were supplied by F. H. Hopkins & Co. is that they are electrically driven. The power is derived from 550 volt, 3-phase, 60 cycle induction motors. The mixers are made to load at the end and discharge at the rear, which makes them continuous in operation. They can also travel by their own power.

REFRIGERATION PLANT ORDER

The Hume Hotel, Nelson, B.C., has contracted with the Armstrong Machinery Co., Spokane, Wash., for the installation of a 3-ton refrigeration plant for general hotel use. It will be operated under the direct expansion service and installed at once. One of the new type Alaskan compressors will be used.

BIG SMELTER FOR KENORA.

There is every indication that Kenora, Ont., will have the biggest plant for the treatment of iron ores by electricity in the Dominion. Plans are about completed for the establishment at Kenora of a gigantic smelter for treating electrically the iron ores of a newly found field near Dinorwic, on the C.P.R. The vicinity of Keewatin Power company's dam within the town limits will be the site of the new smelter, and the 40,000 horse power available at the dam will be utilized. Several thousand men will necessarily be employed, and Kenora will receive a great impetus in every way. The new company, among whom is Cawthra Mulock, of Toronto, have retained the Reese Engineering Co., of Winnipeg, as technical advisors.

RUBBER BELT ORDER.

The Goodyear Tire & Rubber Co., of Canada, Ltd., have received an order for 12,000 feet of Elevator Belting, being the rubber belt equipment of 27 elevators for the Province of Saskatchewan.

CATALOGUES.

The Dominion Belting Co., Hamilton, Ont., are distributing among their customers and friends, a set of pretty girl blotters, emblematic of various well-known flowers.

Butterfield & Co., Rock Island, Que., have issued a new catalogue descriptive of their large line of Screw Plates, Taps, Dies and Reamers. The catalogue includes several useful tables, such as sizes of tap drills, etc. Like most of the leading tap makers, Butterfield & Co. are urging the disuse of the V thread.

The Garvin Machine Co., New York, have forwarded us a copy of their new catalogue, Edition DA, which illustrates and describes some of their numerous machine tool productions, including Profiling, Duplex Milling and Vertical Spindle Milling Machines; Universal Cutter and Surface Grinders, Vertical, Horizontal and Automatic Tapping Machines, Gang Drills and many others. The catalogue is of convenient size—6 by 9 inches and attractively got up.

LET US FIGURE ON YOUR REQUIREMENTS
GALT FOUNDRY CO. GALT, ONT.

T. W. Broadbent, Ltd., Victoria Electrical Works, Huddersfield, England, have issued a new leaflet descriptive of their N type alternating motors for one, two and three phase circuits. A special feature of these motors is the robustness of their construction, both mechanically and electrically; all insulating materials being especially selected with a view to withstanding the high temperatures due to heavy and frequent overloads. The motors are well suited to conditions requiring a motor that is practically indestructible; while at the same time they have a high efficiency and power factor, with small percentage of slip.

The Cleveland Pneumatic Tool Co.'s new Catalogue L has lately reached us. It is very compact, yet complete, and illustrates the numerous high-class pneumatic tools manufactured by the firm; including Riveting, Chipping, Beading and Calking Hammers; Reversible and Non-Reversible Drills; Grinders, Floor and Bench Rammers, etc., etc. All the air drills have annular ball bearings on the crank shaft, a feature which originated with this company, and one which gives considerable gain in power over machines with plain bearings. All the tools and machines are illustrated and described, and the catalogue also contains accurately compiled tables of capacities, arranged for ready reference.

The Browning Engineering Co., Cleveland, Ohio, have sent us a copy of their new catalogue of Locomotive Cranes, which has just been issued. The book is well got up, and illustrated by numerous half-tones, showing their well-known cranes at work under varied conditions. The company makes locomotive cranes of all types, operated by steam, electricity or air. Their general construction is fully described in the catalogue, and impresses one with their apparent fitness and capacity for efficient, reliable and economical service.

"Hydraulic Pumps, Catalogue No. 81" is the title of a new 120-page 6x9 catalogue descriptive of many standard, and several new types of hydraulic pumps. This catalogue, issued and sent free by the Watson-Stillman Co., 50 Church Street, New York, contains valuable information for hydraulic engineers and users of hydraulic machinery.

Hawksley, Wild & Co., Sheffield, England, have sent us a 4-page leaflet containing an illustrated description of the "Brightside" water-tube boiler manufactured by them. The cuts represent 4 and 6-drum types for hand-firing, as also an adaptation of superheater and chain grate stoker. The tubes are straight and almost vertical, and are arranged without headers and caps. The arrangement generally is compact and provides for high efficiency and ease of overhaul and inspection.

The Dudbridge Iron Works, Stroud, Gloucester, England, have issued an 18-page catalogue, descriptive of the Dudbridge new type gas engines and gas producer plants. The constructional details are fully illustrated and described, and show features worthy the attention of all interested in this form of power generation.

Bulletin No. 48, "Resistance to Flow Through Locomotive Water Columns," by Arthur N. Talbot and Melvin L. Enger, records the results of tests of fourteen of the principal forms of locomotive water columns or cranes in use on the railways of the United States. Besides giving the loss of head at various rates of discharge, the tests provide data on the hydraulic characteristics of the valves. Water hammer, relief valves, friction losses through pipe lines, and methods to be used in the design of water service installations are also considered. The bulletin should be of interest to motive power and maintenance of way men. Copies of this bulletin may be obtained gratis upon application to W. F. M. Goss, Director of the Engineering Experiment Station, University of Illinois, Urbana, Illinois.

BOOK REVIEW.

STEAM TURBINES—By Joseph W. Roe, A.S.M.E., A.I.M.E., Assistant Professor of Mechanical Engineering, Sheffield Scientific School, Yale University; 143 pages, 6x9 inches, illustrated; published by The McGraw-Hill Book Co., 239 West 39th St., New York.

This is a short treatise on the theory, design and field of operation of steam turbines and has been written to provide a text-book suited to a short course on the subject, in engineering schools, and also to provide a book for the engineer on the principles and general design of turbines, without going into refined treatment of the more difficult problems entering into that design.

The author treats of all types of turbine and at the end of each section gives a list of references to other works on the subject. The mechanical problems of construction are fully dealt with, and there is an extremely interesting chapter dealing with the relative economy of steam engines and turbines.

Jessop's Best Tool Steel is yet unexcelled for cutting tools of all kinds, and for general machine-shop use.

Wouldn't it pay you to kill those Gear Noises?

On a merry-go-round, the music is employed to kill the gear racket. We don't cite this as a suggestion that a brass band should be put in any shop or office, but pleasant surroundings are just as desirable during working hours as at other times. Employes do more and better work where there is no inharmonious ring and clatter, there is better feeling and less chance of costly misunderstandings, and any man appreciates attention to his comfort.

The change to New Process Pinions really involves no expense. The wear, vibration and power loss—these are what noise indicate—disappear.

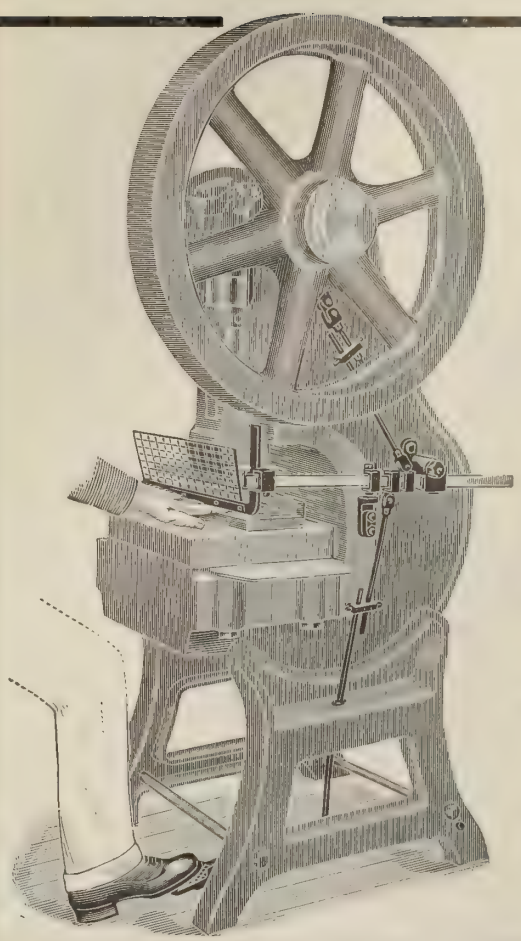
PNEUMATIC TOOLS

The absolute safety and simplicity of transmitting compressed air, its wide range of profitable uses and the economies effected by its uses, give it an indisputable position of supremacy as a means of transmitting power for operating small portable tools.

Pneumatic tools are not delicate, complicated pieces of machinery, but positively simple, rugged little money savers, made to stand rough usage, yet maintain their efficiency.

In "Imperial" designs wearing parts are reduced to the reasonable limit of simplicity, and manufactured to give the greatest satisfaction.



No part of a plant equipment, representing the same investment, will do more to reduce labor costs, increase output and enlarge dividends than a good pneumatic tool equipment. We firmly believe that "Imperial" tools represent the very best sustained value, first costs, maintenance and operating costs being considered. They are thoroughly well designed, embody all practical up-to-date improvements and give very exceptional efficiencies. These features have won for "Imperial" tools their present favored position.

Steptoe Shapers are

GOOD: Because of the care taken in construction.

STRONG: Because the Column, Ram and Base are heavily ribbed and braced and the metal placed where it is needed.

DURABLE: Because all wearing surfaces are hand scraped to standard surface plates and provided with gibs to take up any wear.

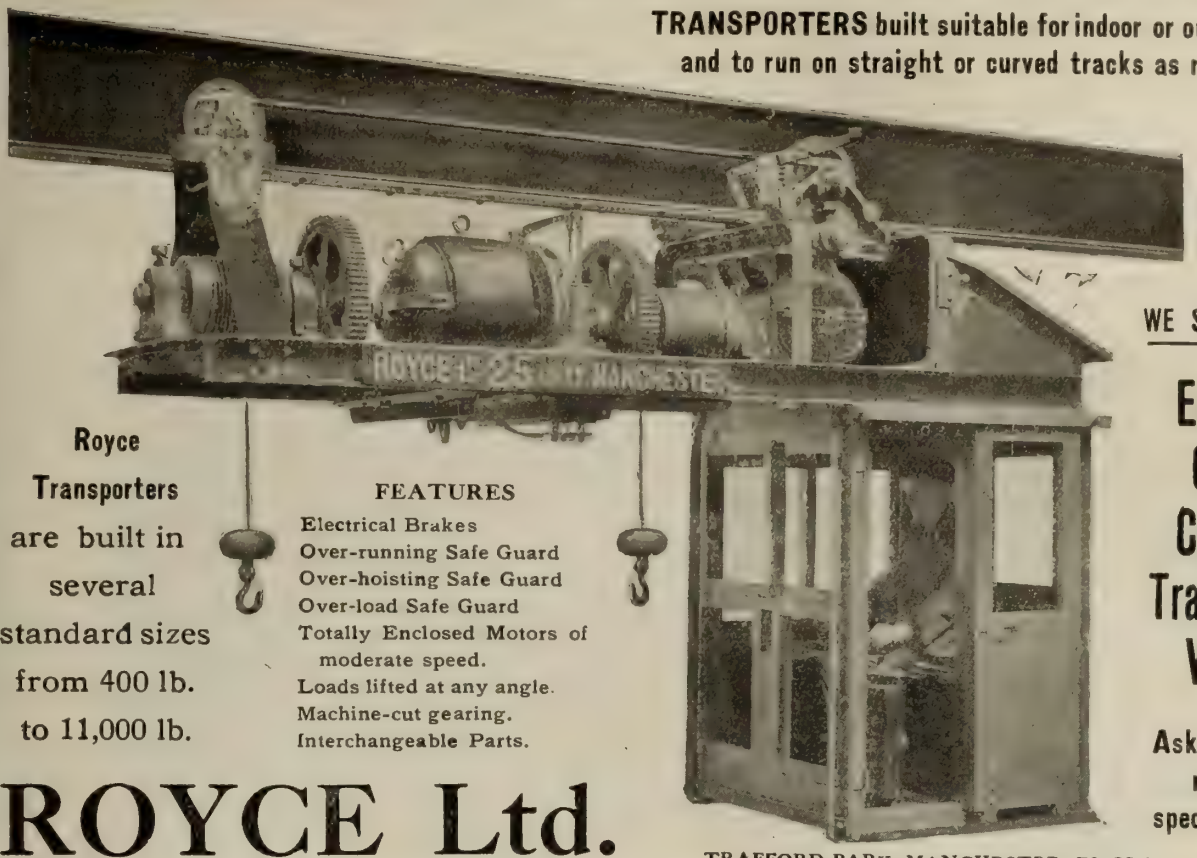
DON'T MAKE THAT CASTING TWICE!

GUARANTEED RESULTS

Shelton Metallic Filler

We guarantee that Shelton Metallic Filler will fill in and completely obliterate ***blow-holes,*** sand-holes, etc., and that it actually becomes part of the casting itself, being just as durable and solid. It can never be detected. THERE ARE MANY METALLIC FILLERS ON THE MARKET, but as is the case with almost everything else, many of these "Metallic Fillers" are made to ***sell***—not for use. SHELTON METALLIC FILLER is made to ***fill,*** and to stay ***filled.*** It cannot be dislodged by the most severe service or the roughest handling.

It is no "patent-medicine" side line with us—we ***must*** sell it to exist—and to sell it we ***must*** make it good, for we can't make money on free samples, or expect "re-orders" if our goods do not prove our claims.



Shelton Metallic Filler is many years old, and has been in use in many of the best foundries in the country for years. ***You*** should give it a trial.

Let us send you a free sample.

LOCOMOTIVE CRANES

AN efficient Locomotive Crane is an economy of gigantic proportion, where weighty or bulky materials must be handled.

ECONOMY
MEANS SUCCESS

in contracting as well as milling operations
We manufacture appliances for both, such as

STEAM SHOVELS, LOG LOADERS,
AUTOMATIC BUCKETS and
ELECTRIC MAGNETS.

Whatever your problem may be, let us suggest a solution which will save you money.

THE BROWNING ENGINEERING COMPANY
CLEVELAND, OHIO.

This Gravity Molding Machine

really is the only one on the market that completes a perfect mold automatically without stripping-plates or hand-work. You cannot afford to be without it.

WE ALSO CARRY

Jar and Squeeze Molding Machine.
Hauck Oil Burners.
Cyclone Hoists.
Acme Parting
Red Facing

The Making of Hollow Castings

The recent introduction of King Kore Kompound has now rendered this, once somewhat difficult, part of Foundry practice comparatively easy.

It has, also, reduced the core expense by more than one-half.

This compound is a black, dry powder, and is used as flour is used, but with one-half the quantity is produced greater and better results.

Its use avoids the danger of swelling or "blowing." The core easily comes out of the casting, and when old cores are ground up, in the rattler, or otherwise, the sand so made is used over again.

The core compound it contains, again becomes a binder under heat of the core oven, as it melts, and so it is used over and over again.

This is Foundry Economy; Flour, Rosin, etc., are now luxuries.

A barrel of King Kore Kompound will be sent "subject to approval" to any inquiring mind.

That is the **Stevens' System** of trying before buying.

I have copies of proportions of compound to sand used and methods followed in core rooms of Foundries in thirteen different States. This information, with other printed matter relative to the subject, will be mailed on request.

I maintain a direct branch at 137 Jarvis St., Mr. J. M. Mayers, Manager, Toronto, Ont., where is stocked a supply of **Foundry Facings, Foundry Supplies, Buffing Compositions,** of my own manufacture.

The stamp of quality pervades them all.

FREDERIC B. STEVENS

Main Office - - - - - - DETROIT, MICH.
Canadian Branch - - - 137 Jarvis Street, TORONTO.

The advertiser would like to know where you saw his advertisement—tell him.

Good cores mean good foundry practice.

Glutrin makes good cores—some people say the best cores.

Robeson Process Company

FRANCIS HYDE & COMPANY

31 Wellington Street

MONTREAL, CANADA

Five years ago, the De Lamar Copper Refining Co. purchased 614 Smooth-On Corrugated Iron Gaskets, for their plant, sizes from 4 to 18 inch pipe.

They wrote us April 14, 1911, as follows:—

Gentlemen:--
Replying to your inquiry as to whether the Corrugated Iron Gaskets which we installed in 1906 in this plant have continued to give satisfaction, we are pleased to state that our steam lines have remained tight and that the gaskets have given no trouble whatever.
Yours truly
LAWRENCE ADDICKS
Superintendent

Just think, not one leak in five years. Why not use SMOOTH-ON GASKETS, and avoid leaky joints and costly repairs?

Our illustrated Catalogue is free. No engineer should be without it.

Smooth-On Mfg. Co.,

JERSEY CITY, N.J.

FOR SALE BY SUPPLY HOUSES

Tune your ear to an

ALOXITE WHEEL

It sounds good—there is no rasping or screeching—just quiet, easy, fast grinding every minute.

A noisy wheel always denotes unnecessary friction heat, lost energy and spoiled tools. There is no economy in using such a wheel. It's always the quiet wheel that does the real work.

Aloxite is hard, sharp and tough—the ideal material for steel grinding; for cast iron, bronze, etc., there is nothing to equal Carborundum

LET US HELP YOU GET THE RIGHT WHEEL IN THE RIGHT PLACE

A GOLD MINE

SAVE YOUR IRON

SLY'S PATENT IRON CINDER MILL
Patented, No. 514097. Patented, No. 841728.

may be at your disposal on your very premises. Look out of your side window or back door and see if you have not an accumulation of cupola dump, and other foundry refuse, which is a total loss to you in its present state. Why not add to your profits and install one of the Sly Patent Cinder Mills to reclaim this iron and be astonished at your former loss and pocket the rich returns from your newly-discovered mine.

Sly's Patent Iron Cinder Mill will save 95% of the iron contained in your cupola dump and gangway scrapings and 75% of the coke. Iron is valuable, then why throw it in the dump? Iron recovered by this Mill is better than machinery scrap. Study economy in a foundry and your profits will increase accordingly. Mill will pay for itself three or four times every year, and we have records of Mill paying for itself twelve times a year. Let us know amount of your daily melt and we will quote. *Write for Cinder Mill Catalogue F.*

We also manufacture Cleaning Mills, Dust Arresters, Sand Blast and Foundry Equipment.

CARBON AND HIGH SPEED STEEL.

Morse Twist Drill & Machine Co.

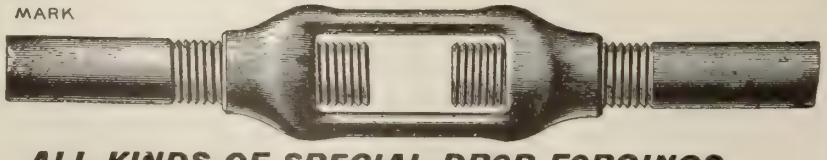
New Bedford - Mass. - U.S.A.

Three Minutes' Grinding puts a new and stronger tang on the shank. It fits the lower slot in the socket.

What Do Your Twisted-Off Tangs Cost?

Keep account for a time of the new drills used to replace those thrown into the scrap heap because of twisted-off tangs, and you will see. These scrapped drills are all right in every other respect.

The "PERFECT" Double-Tang Socket



gives a simple, effective, and inexpensive means of eliminating this cost and putting the drills back in money-earning shape. **Write for Folder A.**

TRADE W B TOOLS OF QUALITY BEAR THESE MARKS W&B MARKS

If It's a Wrench
OF MERIT
We Make It

And *Every Wrench* of our make is guaranteed by that "W & B DIAMOND" TRADE MARK standing for unequalled Quality, Strength and Finish.

You can buy all your Wrenches with that same quality guarantee, as the "W & B" is the *Largest and Most Complete* Wrench line in the world and offers a selection for *Every Wrench Purpose.* Give your jobber a trial order, but be sure you get Wrenches with that "DIAMOND" TRADE MARK. If he does not handle them, advise us and we will ship from our nearest Distributors.

You Can Always Be Sure Of "W & B" Wrenches

because we are sure of them. To pass our inspection each Wrench must meet the quality requirements of that "W & B DIAMOND" TRADE MARK. The "W & B" standard of supremacy is found in the superior quality of steel used, in the care and skill employed in Forging, Milling, Hardening and Finishing. Then we have the knowledge of how to make Wrenches. Talk with your jobber or write us. Catalogue No. 75 C.

"Fenestra" TRADE MARK

What "Fenestra" Fireproof Sash Will do for YOU in YOUR Factory

¶ Protect from fire.

¶ Save insurance premiums.

¶ Prevent burglary by sneak-thieves or tramps.

¶ Admit from 25 to 40 per cent. more light than wood sash.

¶ Ventilate freely, supplying fresh air and removing foul air, smoke, gas, etc.

¶ Last indefinitely—Fenestra sash is impervious to rust, acid and smoke fumes.

¶ Greatly inprove the appearance of your factory and stamp its owner as a progressive man, choosing by common sense instead of cob-webbed precedent.

Don't take your opinions on Steel Sash second-hand. Get a copy of Catalog "F-2" and find out all about them for yourself.

B & S Cutter Testing Fixture

When your gear or formed cutters are sharpened they must be ground with the tooth faces radial or the work which they do will not be satisfactory.

This fixture is designed to accurately test the cutters in this particular. After the cutter has been ground it is mounted on the stud and the faces of the teeth are turned so that they rest, one after the other, on the testing plate which is radial to the stud. When the whole contour of the tooth touches the plate simultaneously the tooth faces are radial.

MARINE ENGINES and PUMPS. SHOE MACHINERY A Specialty

BRASS and IRON CASTINGS. BOILERS and REPAIRS.

That we have exceptional facilities at our disposal for the manufacture of all kinds of Machinery —in addition to our business as Brass and Iron Founders, General Contractors and Shoe Machinery Engineers—has been amply proved this year. In the short space of five months, we built and installed all the Engines and Boilers of the new sister steamers "Levis" and "Lauzon," whose trial trips were a complete success. We make a specialty of all kinds of Marine Engine Work, and shall be glad to quote for first-rate products only.

SHOE MACHINERY. Manufacturers of "Non-Royalty" Machines, Metallic and Goodyear, "Fortuna" Skivers, and "Climax" Presses, Sand-papering, Lasting and Loose Studding Machines.

Wire of every description for Slugger and Standard Screw Machines.

Increase the Efficiency of YOUR Machine Shop by Installing This New McDougall Gap Lathe. It Has Already Proved That It Should Have a Place in Every Shop Where Accuracy is Demanded.

DESCRIPTION

Headstock construction prevents chattering, and deep oil chambers fitted with ring oilers make spindles and bearings self-oiling and always well lubricated.

Tailstock of a special type, and sleeve is clamped by a quick acting locking device. Tailstock is secured to bed by bolts adjusted from the top where they are easily accessible.

Bed, non-springing and webbed, and braced to secure rigidity.

Gap, vibration absolutely prevented by use of brace supports to carriage.

Spindle, high carbon hammered steel in solid chilled cast iron bearings, accurately fitted and self oiling.

Carriage and Apron, non-springing under severest strain, full "V" bearings and flat bearings in addition on front ways.

Double Back Gears give eighteen distinct spindle speeds, suiting lathe to work on widely different diameters.

Compound Rest, with graduated base, accurately fitted taper gibs, end adjusted. Screws in both rest and cross slide read to thousandths.

Friction, Safety Feeds, screw and rod feeds cannot be both engaged at the same time. Quick changes of 1¼, 2½ and 5 times thread being cut.

Gears and Racks, cut from solid and steel where necessary.

Screw Cutting, full range of commercial threads provided for

Equipment, Compound rest, steady rest, follow rest, large and small face plates, wrenches, two-speed, friction countershaft furnished with each lathe.

Accuracy, Strength, Solidity, Wear. These are the paramount features behind all McDougall Machines. Made **to meet extreme demands.**

For Rapid Steel Drawing

Bement Hammers

1600-lb. Bement Double Frame Steel Tilting Hammer.

1500

BEMENT TILTING HAMMERS are guaranteed to deliver a set number of blows per minute.

A special device in valve gear controls the steam cut-off to a nicety, and assures a constant regularity of force, and an unusually rapid succession of blows at any desired steam pressure and any length of stroke.

The action is so sensitive, and yet so positive, that, when once set, it will operate automatically without attention and with exact uniformity until the steam is shut off.

The excellence of the cam motion assures a constant length of stroke.

Hammers can be equipped with dies set square or askew, and with part narrow face for rapidly breaking down stock.

All Hammers are Accurately Adjusted and Thoroughly Tested with Steam or Compressed Air Before Shipping.

The catalog "Bement Hammers" sent upon request.

Cost Reducing Features

An indestructible spindle bearing made of hardened steel and cast iron.

A head construction that gives more effective pulling power at the spindle than any other lathe built.

A patent "compensating V" that permits four times the bearing area between the carriage and bed found on other lathes.

A carriage in which the tool thrust is taken on a bearing the entire length of the carriage, and which positively will not climb the V.

A double-walled one-piece apron which will last as long as the rest of the lathe.

A quick change gear complete in one unit, giving thirty-six changes with two operating levers.

An offset compound rest which can be used without skinning the operator's knuckles.

The centres set back of the middle of the bed, giving greater swing over carriage and permitting the turning of work up to the maximum swing without the tool overhanging the bed.

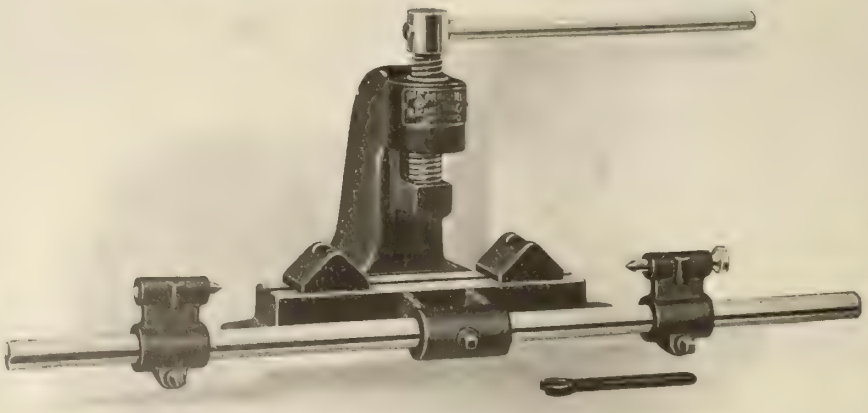
Among The Smallest In Size But The Greatest In Efficiency

Springfield
12-Inch Crank Shaper



While small in stroke this Shaper is heavy and substantially built. The same care is used in its construction as is shown in any of our higher priced tools.

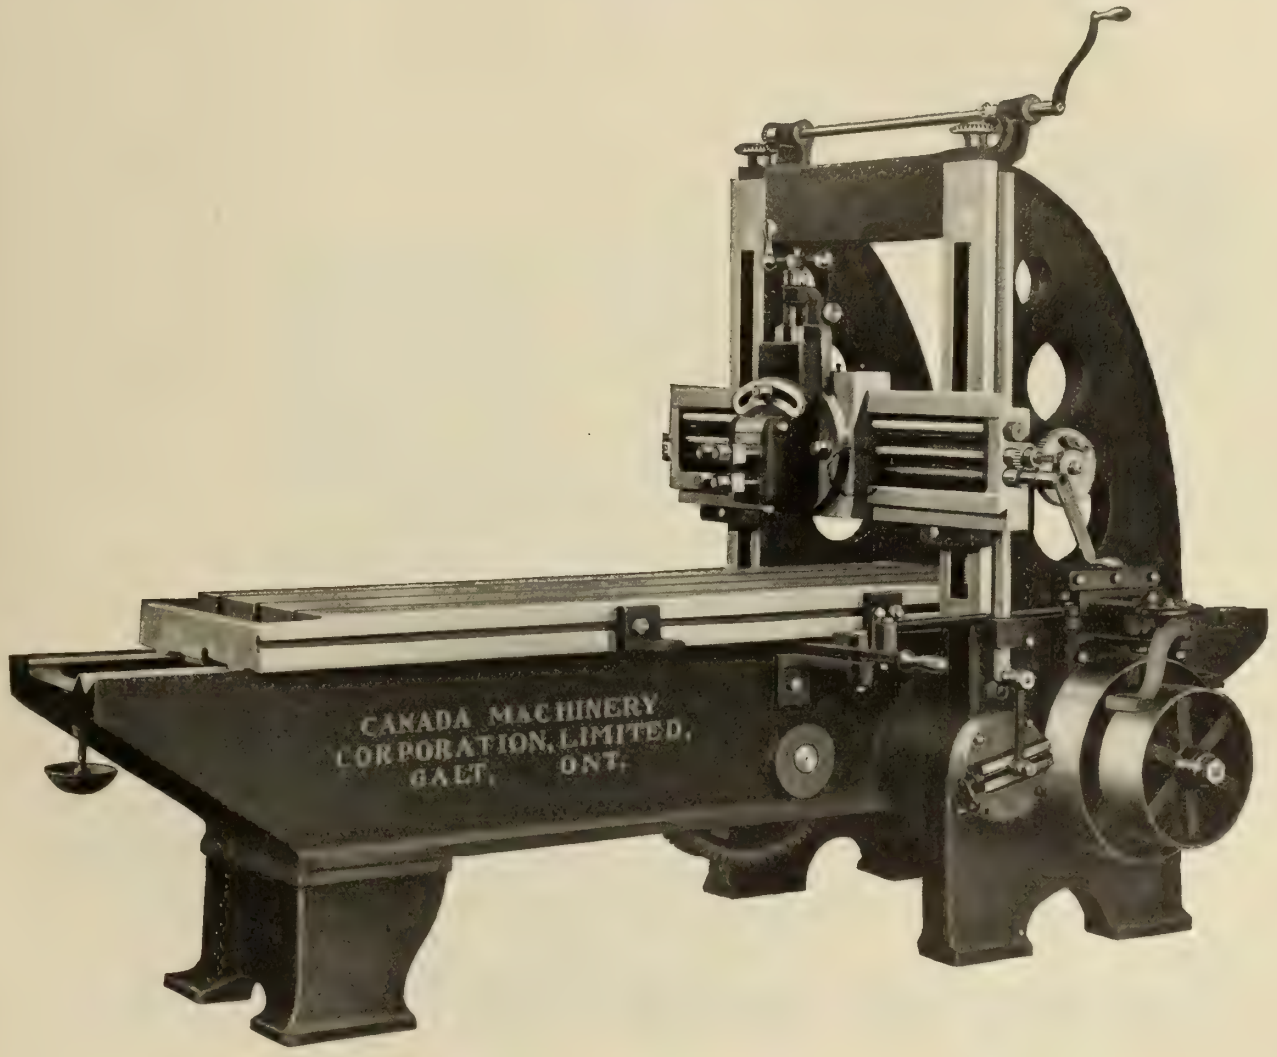
Nearly a quarter of a century's experience is back of Springfield Shapers. And our shapers are noted for their *simplicity*.

Consider these points about the 12-inch Crank Shaper. The vises have steel-faced jaws and a graduated circular base to permit of their adjustment to any required angle, and may be secured to top, face or side of the table. All the handles for operating the machine are placed in accessible positions, and so arranged that any adjustment, either of stroke or position of cross-rail, may be made while the machine is in motion. It is unnecessary to adjust the feed for different heights of cross-rail because it is made to adjust itself *automatically*. Write us for circular No. 111.

This Bench Straightening Press Saves Time and Energy

If you have our Bench Straightening Press you can straighten the work and test it right on the bench.

Compute the time it takes your men to carry their heavy loads from bench to lathe and vice-versa. Consider the time it takes to straighten work with a hammer, and the *loss* of time involved in testing it and perhaps carting it back again to be done all over.



There's only *one* sensible way of looking at the question. Our Bench Straightening Press has its own testing centres, and the first straightening process is also the final. The work will be absolutely accurate and will remain so in the lathe. Straightened right at the bench. *Write for Circular No. 101.*

Cincinnati Cone Driven Millers

IN every shop there is some work on which the cutting is light that can be milled to best advantage on a modern Cone-driven Machine. To meet such requirements we have re-designed our line of Cone Type Millers, Plain and Universal. They have many important features far in advance of other Cone-driven Millers.

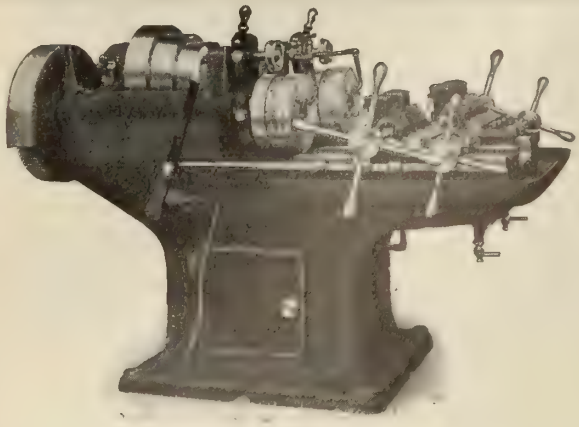
The COLUMN is a complete box of rectangular form.

The FEED MECHANISM is a single unit, assembled complete by men who are specialists on this work. When in place, it is an integral part of the machine. It is located high above the floor—the operator need not stoop to reach the levers. The feed changes may be made within the pratical limits of milling while taking a cut, without inconvenience or injury to the gears, because they all run at moderate speeds.

The FEED INDEX is direct-reading—no chance for confusion or doubt as to the proper lever movements. It is the simplest index used on any machine tool.

All these features make this type the ideal machine for manufacturing small parts and for tool-room use.

We make a complete line of newly designed Millers;



Plain, Universal, Vertical—Cone-driven, High Power

John H. Hall & Sons,

BRANTFORD, CANADA

The Geometric Threading Machine

equipped with one of our STANDARD DIE HEADS, is turning out a large amount of accurate work—work that cannot be done on the usual Screw Machine, and work that cannot be economically done in any other way.

The Die Head with which this Machine is regularly fitted has a range of cutting from 1/4 inch to 3/4 inch, the sizes obtainable being 1/4 inch, 5/16 inch, 3/8 inch, 7/16 inch, 1/2 inch, 5/8 inch and 3/4 inch.

Where fine pitch threads are to be cut on larger diameters, the Machine can be fitted with a Die Head to take care of the work.

The chasers, from time to time, can be renewed at slight cost as they become worn.

Do not confuse our Machine with the usual run of Bolt Threading Machines.

Hendey 24-inch Improved Engine Lathe

IT has taper journals for spindle, annular bearings for same, and lubrication controlled by ring oilers. It has mounted change gearing, giving 36 different threads and feeds. Threads not shown on index, including metric pitches, can be cut with the aid of a few extra change gears. It has automatic stop for carriage in either direction. Reversing travel controlled by lever located at right hand end of apron, allowing the spindle to run in one direction. Carriage is heavy and substantial but has remarkably easy traverse along bed by means of hand wheel. This easy movement appeals to the operator. Workmanship and accuracy of our machines guaranteed to be the very best.

HAVE YOU EVER SEEN A NO. 205?

No. 205. Double Circular Saw.
Patented Jan. 26, 1908.

If you did, you know it's the finest saw ever built for pattern shops.

There is so much to tell about this machine that we have gotten up a special booklet about it. You are entitled to a copy and it will be sent upon receipt of your name and address.

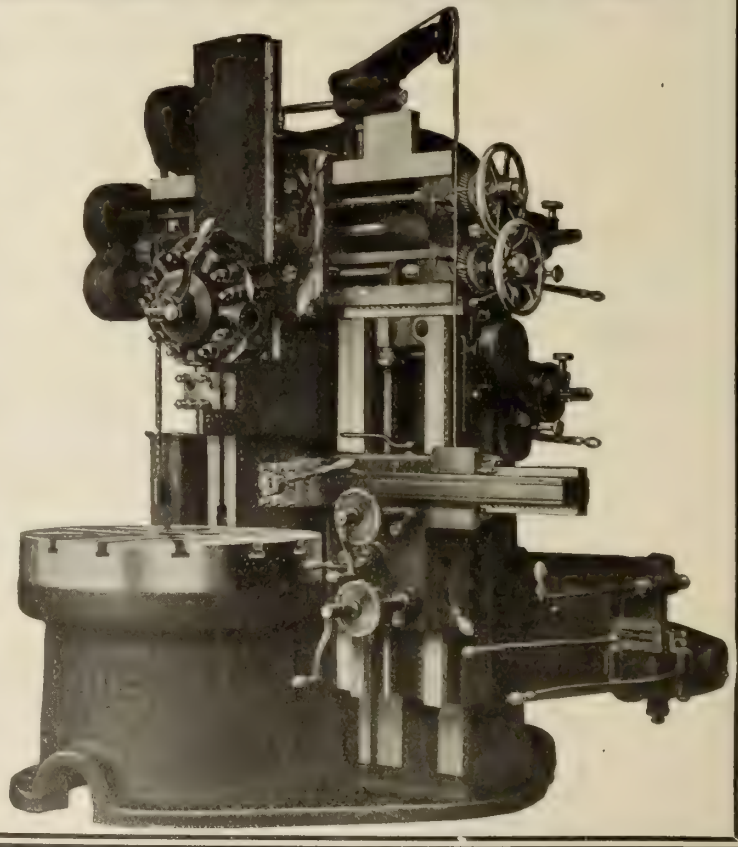
Built like a machine tool throughout, but in such large lots that the price is right.

Don't forget to write for the book.

J. A. FAY & EGAN CO., 362-382 W. FRONT STREET, CINCINNATI, - OHIO.

One Machine That Replaces Two Others and Does the Work of Either in Less Time

On all Face Plate Work Within Its Range

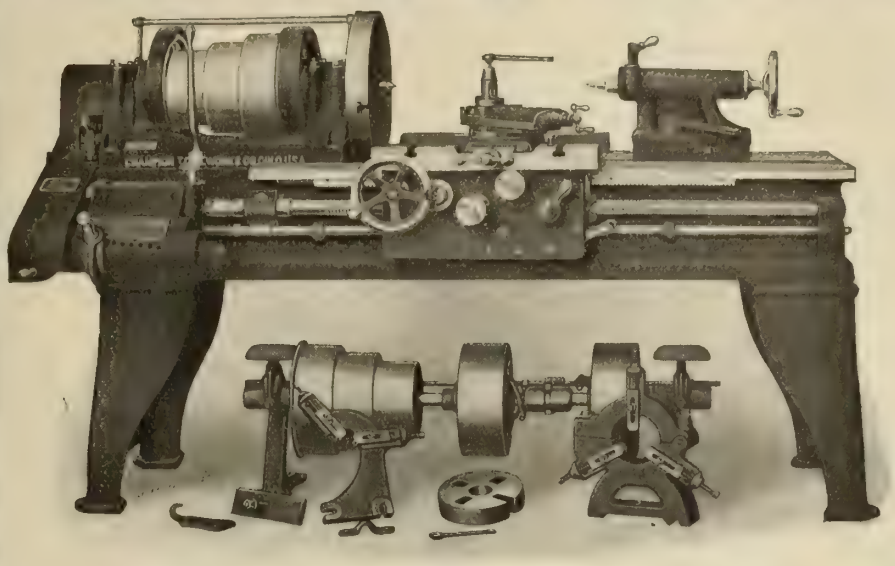


On all work within its range, the Vertical Turret Lathe replaces both the Vertical Boring and Turning Mill and the Horizontal Turning Lathe. It ***combines*** their good features. Thus it takes the place of either one of them with all the valuable features of the other ***added.*** But in combining the two, other features were developed which are exclusively the Vertical Turret Lathe's. Like a boring mill, it is heavy and rigid, capable of doing heavy cutting. Like the horizontal turret lathe, its turret provides a means of holding tools in instant readiness for a sequence of operations.

Unlike either of them, it has a Side Head for more tools, which can be brought into use simultaneously with those in the Main Head—Multi-cutting.

Unlike the horizontal machine, there is no overhang of the work—the alignment of table spindle is self-preserved.

Unlike the boring mill, the ***control is centralized*** —time-wasting steps are eliminated. The similarities show that the Vertical Turret Lathe does all the work within its range, as well as ***both*** these machines.



Let us send you our interesting Treatise on Face Plate Work C-15—Free. It has the details.

"Gridley" Automatic TURRET LATHE

"GRIDLEY" SINGLE SPINDLE

For Rapid, Convenient and Economical Service

Work of greater length and more complex character than usual can be easily accomplished with the "GRIDLEY" Turret Lathe.

It differs from all other automatics in the manner of supporting the tools, and in the arrangement of the tool holders on the tool slides of the turret.

On all other automatics there is an overhang of the tool. This overhang prevents the performance of accurate work, because the method of supporting the tools does not permit as heavy cuts or as coarse feeds.

Saves time and money, as one operator can attend to several machines at once, and can use tools tandem on each machine when rapid production is necessary.

"GRIDLEY" Automatics assure greater accuracy, larger output and wider range of work.

We manufacture both Multiple Spindle and Single Spindle Automatic Lathes. **Write us at once for particulars.**

IMPROVED POWER HACK SAW

The high efficiency and durability of this machine is the direct result of the superior grade material used, and the employment of skilled workmen.

It cuts bars 6x6 inches, either round or square, and is so constructed as to require no attention after work is put in vise, and stops automatically when piece is cut off.

The **Improved Saw Guide** is worthy of your special notice, as it keeps the saw perfectly in line at all times.

D. McKenzie, Guelph, Ont.

Valley City No. 3

This Tool and Surface Grinder has an unequalled production range where quantities of key-fitting, punch, die and tool sharpening are concerned.

Base is cast solid to avoid vibration and permit high speed. Convenient and rigid knee and table operated by hand wheel, holds work solidly in any desired position.

Table, 11 x 20 inches, has a vertical travel of 12 ins. on the guides and may also be equipped with a reversible sliding table. Floor space required, 28 x 20 inches. A very convenient all-around machine for general shop or tool room grinding.

Send for catalog of grinding and polishing machinery.

High Speed Steel Has a Solid Foundation In a Name That Means Something

Cutting speed attained on cast iron: Roughing cut, 140 ft. per minute—finishing cut, 210 ft. per minute.

In NOVO SUPERIOR you secure a materially increased speed over the high speed steels now in use, the highest quality, greatest toughness, longest life (3 times that of any other) and exceptional ability to cut very hard materials. The cutting edge retains its sharpness from 3 to 4 times longer than other high speed steels. Hardens in oil, air or water, and is now carried in stock in our warehouse in all current sizes, flat, squares and rounds; annealed and unannealed.

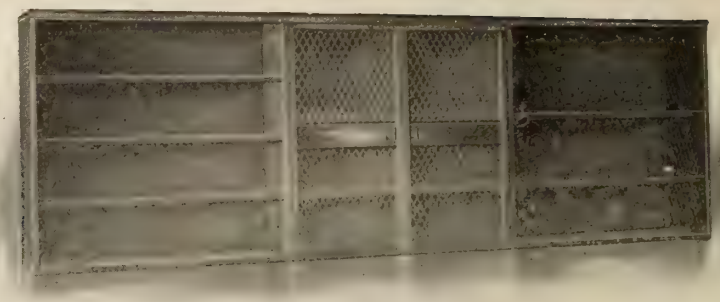
"CROWN"
SAND RAMMERS

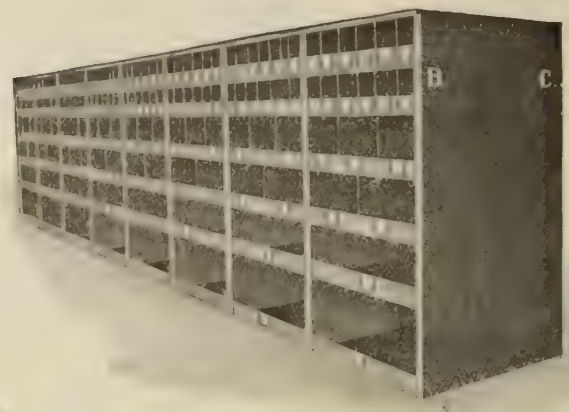
The absolute safety, simplicity and economy of transmitting compressed air make it admirably adapted to driving portable tools, and are factors which have done much to place the pneumatic tool equipment well up on the list of dividend-earning machines.

The application of these pneumatic labor-saving devices to industrial problems has probably reduced labor costs more than any one invention since that of the steam engine.

The "Crown" Sand Rammer is one of the latest pneumatic appliances to be added to the foundry list, and is one of those very essential elements of the modern equipped foundry.



Records of ramming and peining time from representative foundries all over the country show that a man with the "Crown" Rammer will prepare a flask in 15 to 25 per cent. of the time taken by hand, and the mould is more uniform, and a better casting is assured.



They are light, of convenient length, operate freely and consume but very little air.

Made for Bench and Floor Work. *Descriptive Pamphlet 8108*

Has Your Factory Plenty of Light and Fresh Air?

That these are *absolute necessities* in modern factory and office buildings no man who has a shred of progressiveness in his make-up can argue.

Poor daylight and insufficient ventilation mean tired employees, short days, big lighting bills and decreased output.

Yet the ordinary wood sash for factory buildings, if of sufficient size, is so heavy and clumsy in structure that it is not only very *expensive* but *obstructs a large part of the lighting area*, and the difficulty of opening it, particularly in cold or damp weather, prevents proper ventilation.

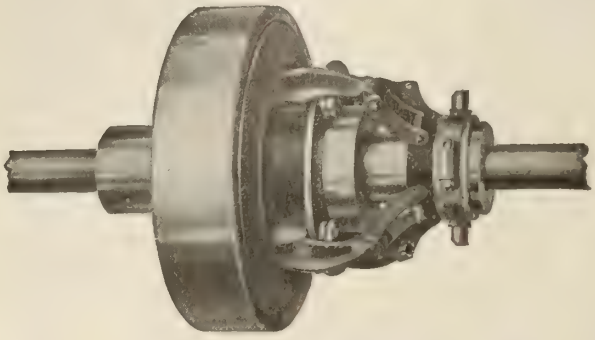
"Fenestra" Solid Steel Sash

is a light, strong steel frame and sash combined, admitting from 25 to 40 per cent. more light through an opening than wood sash.

Not only does it increase the effective lighting area by occupying less space itself, but, because of its almost unlimited resistance to wind-pressure, windows may be built of it in almost any size.

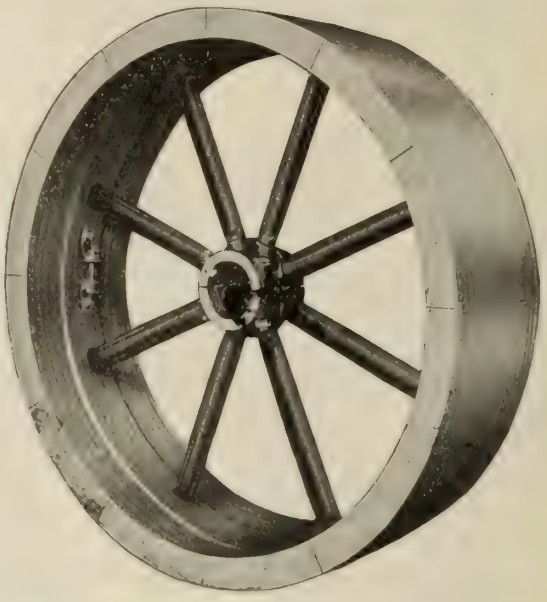
"Fenestra" Sash encourages your employees to properly ventilate their work-rooms by making it easy and handy to open and close the ventilators. "Fenestra" ventilators do not swell in damp weather nor freeze up in winter. Replace the foul air and the smoke and gas-laden atmosphere in your factory with fresh air, give your employees plenty of daylight and watch the effect on your output and lighting expenses.

Bear in mind, also, that "Fenestra" Sash are *fireproof* and materially lower insurance rates.



They are made in any size or shape, and are always built to supply individual needs.

If you are planning or erecting an industrial building of any kind that you intend to make permanent let us send you our "Fenestra" catalogue. A post card brings it to your desk. Address "Steel Sash Branch."



STEEL AND RADIATION, LIMITED

TORONTO: Fraser Avenue **MONTREAL: 138 Craig Street West**

The POSITIVE Line

Combined Jaw and Friction Clutch

Combination Split Wood Rim Steel Center Pulley

A Talk on Clutches

While the present commercial types of friction clutch possess the necessary flexibility, yet the difficulties and extravagance in the consumption of power, arising from wear and slipping of the friction blocks with continued use in driving the load, has placed them in the class of low-efficiency mechanisms. This undesirable factor offered an opportunity for needed improvement in clutch design.

In the **POSITIVE** Combined Jaw and Friction Clutch the low-efficiency feature has been overcome and both a durable and dependable appliance perfected. The frictions are used only to pick up the load and bring the speed of the driven shaft up to that of the driving shaft; then the jaws lock and transmit the power, the frictions releasing. Thus, the **POSITIVE** Clutch embodies the flexibility of any clutch, but it is different in that it is a positive drive—no slipping—a 100 per cent. efficiency appliance.

Can you afford to run your plant without the clutch that users tell us every day has a most remarkable feature—the Positive Steel Jaws—that cannot slip, the clutch that **does** save power.

Want our new catalogue, "The **POSITIVE** Line?"

A Talk on Pulleys

There are pulleys and pulleys, and pulleys. Some are heavy and give a stolid serviceableness like an old hob-nailed boot; but they are in no wise efficient, nor modern. Others are light; and while they do show greater efficiency, this factor has been accomplished by sacrificing strength and durability in construction. Then, again, there are others that are in a measure light and strong, yet have a low-rim belt contact. It was up to somebody to build a durable, and at the same time, efficient pulley.

The **POSITIVE** Combination Split Wood Rim Steel Center Pulley satisfies every advantageous exaction. The wood rim is waterproofed and gives high belt contact; the steel arms, inserted into the rims with steel pins and forced into the hubs under enormous pressure and upset, assure low wind resistance and great strength; the malleable hubs with the cast iron bushings grip the shaft like a vise. It is split, easily installed, light, durable, and highly efficient.

Just consider whether you ought not to have in your shops the modern pulley, the efficient pulley, the pulley that has the good points of them all—and none of the bad ones—the pulley that **does** save power?

Want our new catalogue, "The **POSITIVE** Line?"

GOODYEAR

Power-Saving Rubber Belting

Goodyear Rubber Belting stands for power saved and money saved. It is built up of plies of rubberized fabric cured and vulcanized into one solid piece. It neither slips nor stretches. It has the cohesiveness of rubber with the enormous tensile strength of close woven, long fibre cotton fabric from which ***all stretch has been taken out.***

Goodyear Rubber Belting is manufactured by a process that makes it proof against steam, water, weather and rot. Made in all three grades and all sizes. For Pulp, Paper, Saw Mills—***all*** mills where horse power transmitted is large and demand for tensile strength great. Used by biggest lumber mills and manufacturing plants in the Dominion. ***Outlives, outlasts*** all other belts.

Rot-Proof Mill Fire Hose

Goodyear Underwriters is a hose built to meet the specifications of the Associated Factory Mutual Fire Insurance Companies. Tube used of highest grade NEW rubber. ***Won't*** harden or crack with age. Special circular woven fabric with least expansion or elongation under pressure. Antiseptically-treated to make it rot and mildew proof.

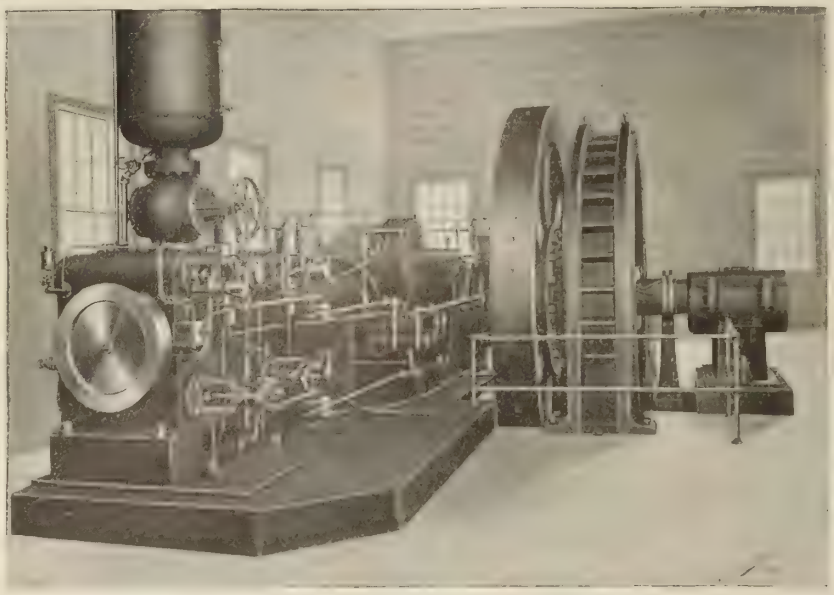
The strongest, most reliable hose for all mills and factories. Insist on ***Goodyear Underwriters, the hose with the black and yellow stripes.***

Non-Chipping Conveyor Belts

Built for all purposes. For conveying crushed stone, grain, coal, ore, etc.

Made in all thicknesses of face to suit requirements of buyer. Rubber face made of toughest stock possible, to prevent cutting and chipping. Gives longest, most enduring service.

We also manufacture other rubber goods such as tires, all kinds of hose and belting, rubber packing, etc.



Write us to-night for catalog and prices.

The Waterous Engine Works Co., Ltd., Brantford, Canada

"THE ONLY METAL"

Magnolia has made its friends and reputation by such instances as are cited in the following letters, and it is just such trying conditions that bring out the true worth of Magnolia in strong contrast with all other bearing metals of whatever kind:—

Dear Sirs:— West Irvine, Ky., Dec. 8, 1910.

I have used lots of MAGNOLIA METAL, in fact **I will not use any other.** I am running a 200 H.P. Automatic Engine **heavy** loaded. I took charge of it four years ago when I found it in bad shape. It was reported to me that I could not hold Babbitt Metal in the Quarter Box or crank brasses which I found to be true. I made an order for some "Magnolia" Metal and used it in both places and have never had any trouble since, in fact they hardly run warm. I believe it to be the **only** metal and will advise all Engine men who have trouble with hot boxes to try it and they will get out of trouble **sure.**

Yours respectfully,
Charles Barkleroad, Engineer,
MOWBRAY & ROBINSON LUMBER CO.

Gentlemen:— San Francisco, Cal., Jan. 27th, 1911.

Am an Engineer and have had dealings with your bearing metal and have found it an A No. 1 all around bearing metal.

Have used it in gas and steam engines which I have built, and am now building a direct connected dynamo engine to run at 500 R. P. M. The gas engine runs at 1800 R. P. M., and I have inquired from the people who are now using it and received word that the metal (Magnolia) is in first class condition after a very severe test; engine running day in and day out without any excessive use of oil, and bearing set up snug, load being very uneven.

MAGNOLIA is the **only** metal in my belief that would stand such use.

I remain Yours truly,
WILLIAM SCHINDLER, No. 105 Andover Ave.

Gentlemen:— Roanoke, Va., Dec. 17, 1910.

For the advantage of all engineers, it affords me the greatest pleasure, with over 15 years' of Sea and Shore experience, to recommend MAGNOLIA METAL as being the most perfect bearing. It surpasses all other metals used for that purpose. Among its many advantages are its long wear and its very high test of anti-friction; it can be easily worked; it requires less oil and will wear longer than any other metal I have ever used.

While stationed on the U.S. Solace from 1893 to 1900, on our voyage from Ney York to Manilla while going through the Suez Canal in the Bitter Lake, we had an occasion to refill our high-pressure crank-pin brasses with Magnolia Metal. The bearing was well fitted to the crank-pin and adjusted. Upon reaching Manilla this vessel was ordered to the Pacific Asiatic Station as a Naval Transport and Supply Ship, and was run very hard, making constant trips between Manilla, China and Japanese ports, and San Francisco, U.S. When I left the vessel, we had made a run of over 50,000 miles. This bearing after being readjusted, I left in perfect condition.

Very respectfully,
O. BRAGONIERS, W. M. U. S. N.

Buffalo "B" Volume Exhausters

have a decided advantage over the usual type in the solid, one-piece peripheral shell.

Not only is this construction very rugged and strong, but the absence of joints under pressure in the shell prevents leakage of air and waste of power. The blast wheel is strongly built, accurately balanced, and, together with the extra long oil-ring bearings insures smooth, easy and quiet operation.

BUFFALO EXHAUSTERS are especially adapted or handling dust and refuse from emery and buffing wheels and tumbling barrels; and smoke, gases and fumes generally. You can always depend on efficient, reliable operation.

A wide range of sizes and capacities make it easy for you to select just the one for your requirements. Ask for catalog 178-LD and prices.

OILDAG

(Registered Trade Mark)
Deflocculated Acheson-Graphite, Dag and Oil.

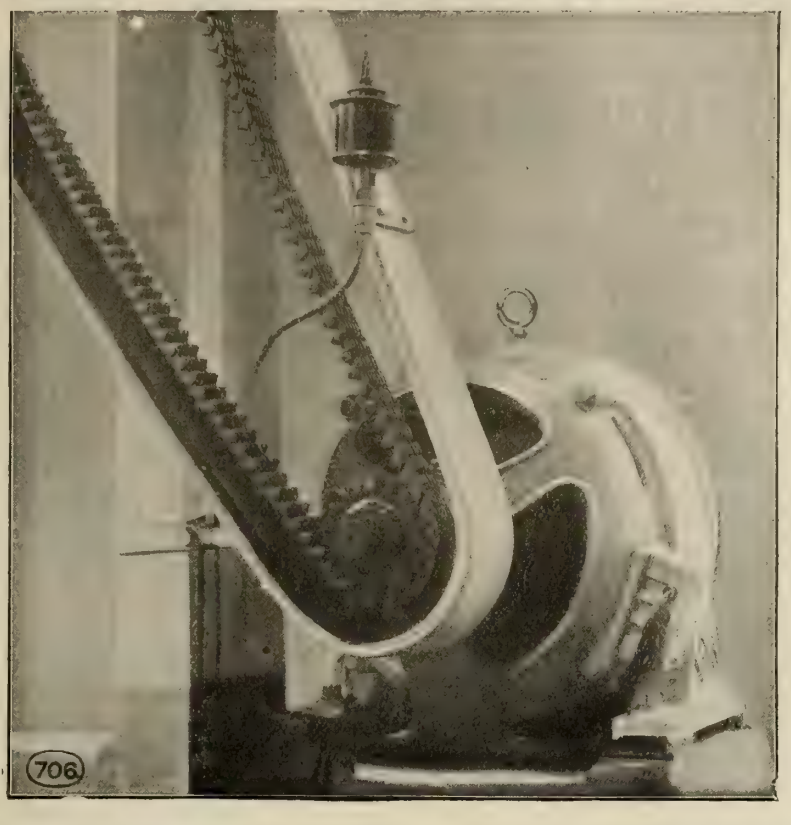
Made in Canada.

Graphite does not dissolve in any liquid or break under pressure, and these qualities, added to the unctious softness and purity, together with its non-coalescing nature, make Acheson-graphite ideal for lubrication purposes.

The process of deflocculation takes Acheson-graphite powder so fine that 99% of it will go through a sieve having 40,000 meshes per square inch, and sub-divides each grain of this finest powder into many still smaller particles—so small that they cannot be seen through a strong microscope.

Oildag is this deflocculated Acheson-graphite suspended in oil, where it neither floats or sinks, but is evenly distributed throughout. Oildag will flow anywhere the oil alone will go.

Mr. Robert A. Ross, E.E., of Ross & Holgate, Consulting and Supervising Engineers, Montreal, writes:



"As my firm are constructing and operating steam plants, we have wished to use a mixture of graphite and oil for cylinder lubrication, but have been prevented by the fact that the graphite settled out of the mixture. **This difficulty you have overcome,** and we are now assured of the best lubrication in the world, especially in superheated steam practice."

The Montreal Technical School, Its Mission and Equipment

By L. G. Dennison, B.A., B.Sc., Montreal

The Rapid Growth and Development in Canada of Mechanical and Electrical Engineering Pursuits, and the Desire to Excel in These Competitively With Other and Older Countries, has Called Forth the Necessity for Facilities and Opportunities, By Which the Practical Work of the Factory may be Turned to Better Account Through a Judicious Admixture of Technical Training. Technical Schools are in Project by all the Leading Manufacturing Centres of our Country, and That of Montreal Which Forms the Subject of this Article, is Among the First of its Kind to be Completed and Open for the Reception of Students.

THE lack of an efficient technical training institution has been keenly felt for some considerable time in Montreal, and while efforts have been put forth on various occasions to deal satisfactorily and successfully with the question, only recently did these assume that definite shape, the culmination of which has been the building and equipment of a Technical School, costing approximately $825,000.00, and creditable to Canada's Metropolitan City.

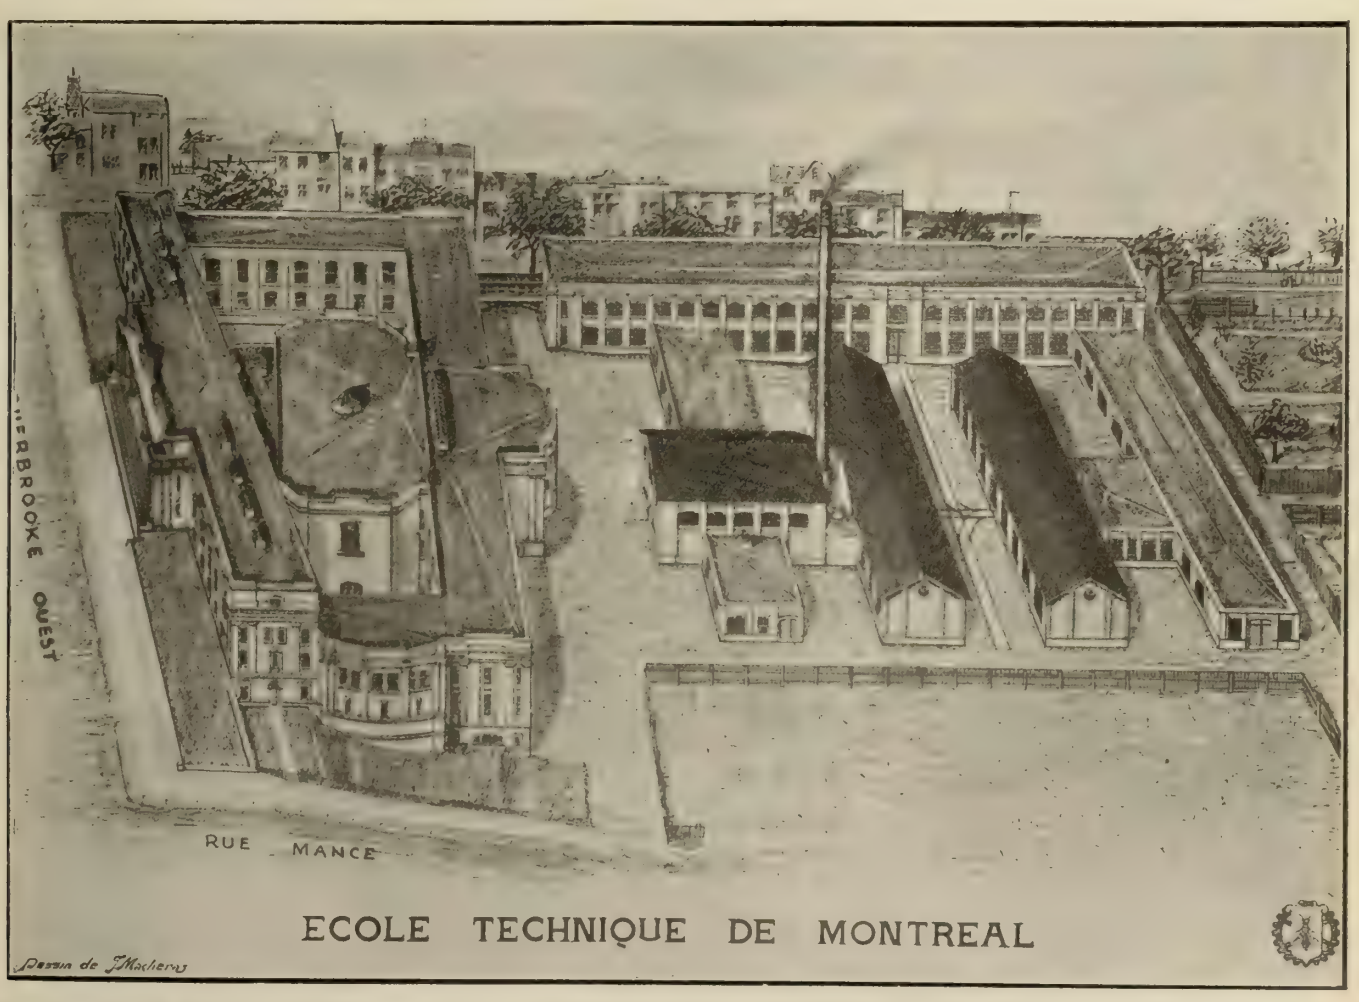
Foundation and Buildings.

Founded, built, equipped and annually subsidised by the Provincial Government of Quebec, and in receipt of a large yearly grant from the City of Montreal, this school is intended to provide adequate and complete instruction in manual trades generally, from the theoretical and technical standpoint, at moderate fees, to day and evening students. Its location is 70 Sherbrooke Street West, and the birds-eye view, fig. 1, gives a good idea of the lay-out and ground covered. The buildings are arranged in two distinct sections: the main structure being on Sherbrooke Street, and the workshop in the rear. The ground measurement is 153,000 square feet.

Main Building and Organization.

The main building which is wholly fireproof, comprises the following. The offices of the Adminstration, several suites used for teaching, including six class rooms, two amphitheatres with seating capacity of 100 each; physical and mechanical laboratory, chemical laboratory, store rooms for materials, museum of industries, library, etc. In the centre there is a large graded semi-circular amphitheatre with seating capacity for 600.

The different sections of the main building offer ideal conditions from the standpoint of comfort and hygiene. The class rooms are large, and equipped to secure complete satisfaction with respect to light, ventilation and heating. A commodious waiting room, toilet rooms, shower baths, and appropriate furniture throughout, conspire to impress one that expense and effort has not been spared to provide a thoroughly up-to-date establishment for its particular purpose. It is proposed to aug-



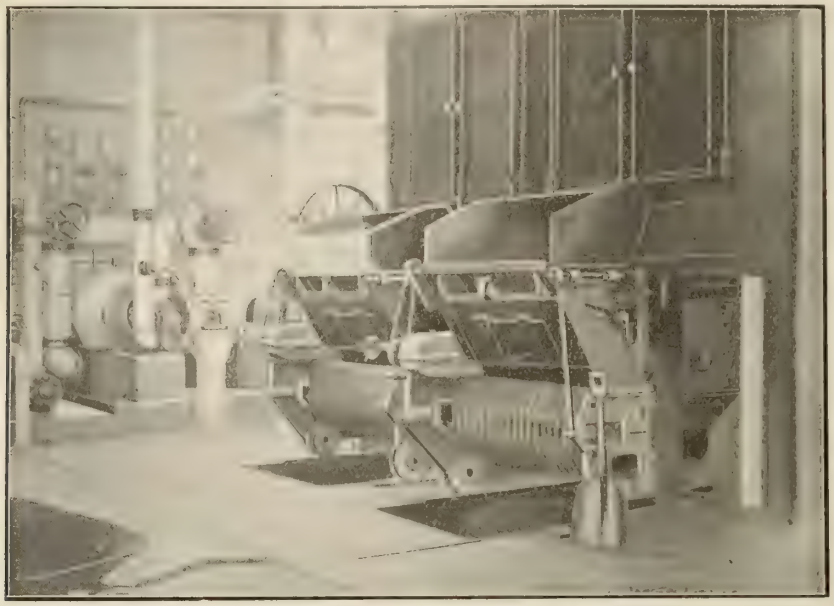


FIG. 1.—BIRDS-EYE VIEW, MONTREAL TECHNICAL SCHOOL.

ment the equipment and teaching apparatus by directing the work of the students accordingly, during each school course. Instruction will be given in both languages, French and English.

Work Shops and Power Plant.

The workshops are laid out on similar lines to those of modern industrial concerns; in the centre is the power house, and around are the foundry, machine shop, smith shop and electrical laboratory.

The Power House—Montreal Technical School.

The boiler room equipment consists of two Babcock and Wilcox boilers and one Delaunay-Belleville marine type boiler. The B. &. W. boilers have chain grates, operated by a Miller Bros. & Toms engine. The heating apparatus for all the buildings is installed in the boiler room.

In the engine room are installed four electrical groups with direct connection, as follows:

1—One of 25 K.W., consisting of a gas motor Duplex, with Canadian General Electric dynamo;

2—One of 35 K.W., consisting of a Robb-Armstrong horizontal steam engine, with Canadian Crocker-Wheeler dynamo;

3—One compound vertical Bellis-Morcom engine, connected to a 75 K.W. Westinghouse dynamo;

4—One Goldie-McCullough Corliss engine, connected to a 125 K.W. Allis-Chalmers-Bullock dynamo.

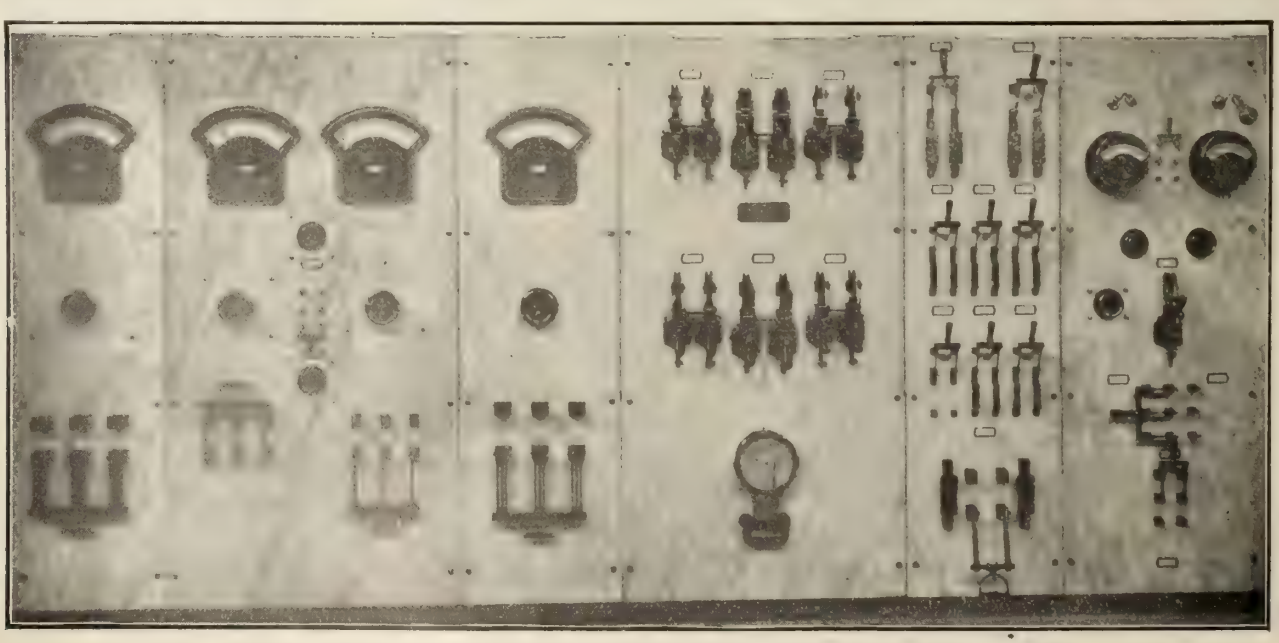
An air compressor for the foundry, a storage battery with capacity of 200 ampere-hours, and switchboard for the control of the light and power, also form part of the engine room equipment.

The Switchboard.

In keeping with the high quality and finish of the various units, is the switchboard fig. 2, built and designed by the Hill Electric Switch & Manufacturing Company, Montreal. It consists of two feeders, one accumulator, and three generator panels of polished white Italian marble, which furnish a most attractive background for the highly finished copper fittings. The feeder panel, from which radiate the various power circuits, contains a Bristol watt-hour meter for recording total station output, and three double pole plain overload Condit circuit breakers. The lighting feeders are controlled by knife switches, with enclosed fuses on the face of the board. The accumulator panel has besides the meters, an underload breaker, a battery rheostat, and an eleven point end cell switch. The generator panels are equipped with Weston flush-type ammeters, of range 150 per cent. of generator output; and have three pole knife switches with fuses on the rear of the board. The voltmeter, fig. 3 on a swinging arm at the extreme left, can be made to indicate either the bus bar voltage, the voltage of any machine, or the drop of potential between bus bars and ground. The marble slabs, 7 feet high and two inches thick, rest on the floor thirty inches from the wall.

Machine Shop.

The machine shop has an area of 11,340 square feet, and contains the following machines, grouped in three sections, each driven by a 15 H.P. motor. Ten plain lathes of 10 inches, twelve screw cutting lathes of different makes from 12 inches to 18 inches, one Pratt & Whitney tool-room lathe; one geared-head Hendey lathe; three screw machines, one of which is automatic; four shapers, two planers; one seven-inch slotting machine; eleven drills from ten to twenty inches; one Brown &



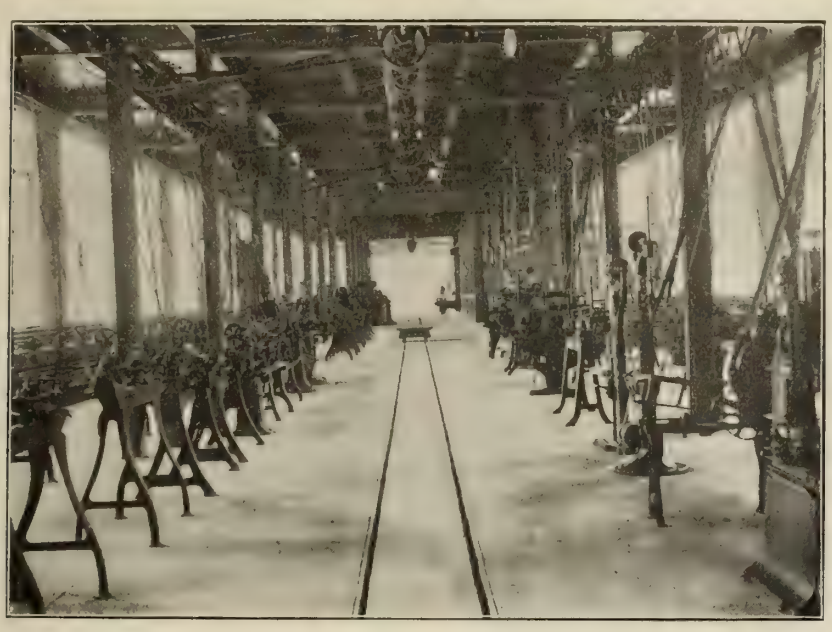


Fig. 2—Switchboard by the Hill Electric Switch Co., at the Montreal Technical School.

Sharpe universal milling machine ; one plane and one vertical milling machine; one profile milling machine ; one pentagraph milling machine ; one universal grinding machine ; one gear cutter ; five tool grinders ; one buffer ; two centering machines ; two mandril presses and a two ton portable crane.

The Machine Shop—Montreal Technical School.

In addition to the above, there are the following large machines, each driven by its own electric motor ; six screw cutting lathes with attachments, one thirty-inch vertical lathe, one chucking lathe, one three foot radial drill, one horizontal boring mill and one floor planer. The space reserved for erecting is served by a three ton traveling crane. The tool store contains a full line of hand tools, measuring and tracing instruments, such as usually used in the best shops, also two Stewart combination gas furnaces..

Eighty vises, and 160 sets of individual tools complete the installation.

Forge.

The forge has an area of 5,210 square feet, and comprises twenty-four Sturtevant forges, twenty-four anvils, and one Buffalo Heating Furnace. The draft is underground and is produced by a 9 H.P. electric fan, while a 4 H.P. electric motor provides the necessary blast.

The other equipment consists of a steam hammer of 170 pounds, one belt driven hammer of 75 pounds, an emery tool grinder, a bar shear, a post drill, two swedge blocks, two blacksmith vises and one tool bench and vise.

Foundry.

The foundry has an area of 5,210 square feet, and is provided with one King cupola of two tons capacity per hour, one oil melting furnace, a Piat combined cupola and a 200 pound crucible furnace. This section is served by a trolley of two tons capacity. An underground installation of compressed air provides for the working of the elevator and other pneumatic tools and machines.

Other foundry equipment consists of two molding presses, one core machine, one coning machine, two core ovens, one sand sifter, one sand mill, one sand mixer, two snagging wheels, one torch heater and molder's benches for twenty-four pupils.

Wood-Working Shop.

The area of the woodworking shop is 6,811 square feet, and the machinery includes eight power wood lathes, four electric driven lathes of variable speed, one electric band saw, one circular saw, one gig saw, one buzz planer, one pony planer, one mortising machine, one tenoning machine, one drill, one shaper, two grindstones, one trimmer, one automatic band saw filing and setting machine, one knife grinder and one band saw brazer. There are thirty benches, with two separate sets of small tools each.

Electrical Section.

The electrical shop, covering an area of 2,714 square feet, adjoins the machine shop, thereby allowing use to be made of the latter as required. The following machines are installed :

One armature banding and heading machine, one notching press, one shear, one pair of smoothing rolls and one buffer.

Annexed is an electro-dynamics laboratory, containing the following five groups of rotary transformers :

1—One single-phase asynchrone motor coupled to a direct current dynamo.

2—One direct current motor coupled to a three phase generator.

3—One series dynamo with shunt dynamo.

4—One six-change commutator.

5—One direct current motor coupled to an alternator giving single-phase, two-phase, or three-phase current, as desired, and the switchboard already described, which provides for electrical connections and measurements, as desired for experimental purposes.

Heating and Ventilating Systems.

The system of heating adopted, is that known as "Forced Hot Water Circulation," and is designed to be operated in connection with a high pressure power plant, utilizing exhaust steam from engines, pumps, and other apparatus. The heating medium, hot water, is circulated from the power house through the different buildings, by steam driven turbine pumps. The installation comprises two large heating tanks, one for exhaust, and the other for live steam ; so arranged that when the amount of

The Blacksmith Shop—Montreal Technical School.

exhaust steam available for heating is insufficient to maintain the desired temperature in the buildings, an automatic valve opens, and allows the water of circulation to pass through the live steam heater before being forced through the buildings.

The particular features of this arrangement, consist in utilizing every

The Foundry -Montreal Technical School.

pound of exhaust steam before live steam is requisitioned, and the consequent absence of back pressure on the engines. During many weeks of operation under severe conditions last winter, the temperature of water returning to the power house was less than ten degrees below the out-going temperature, and several occasions dropped only two degrees.

The buildings are ventilated by means of large ventilating fans and steam tempering coils, the temperature of the whole being regulated by the Powers System of Automatic Temperature Control. Thirty cubic feet of fresh air per minute per pupil is supplied and exhausted in all class rooms, and liberal ventilation given in the work shops. Another interesting feature of the mechanical equipment, is the vacuum cleaning outfit provided for all portions of the main Academic Building.

The heating, ventilating, vacuum cleaning, and major portion of the electrical installation were designed and supervised by Huey & Bellanger, consulting engineers, since incorporated under the name of the Canadian Domestic Engineering Company, Limited, 5 Beaver Hall Square, Montreal.

The material and cuts for this article, were furnished by the courtesy of the school management, the consulting engineers and the different contractors.

SPUR GEARS.

By G. D. Mills, Montreal.

THE immediately preceding example, in our August issue, determines the load on the wheels from a known velocity and required horsepower. Many machines are, however, subjected to shock loads which double the stress on the teeth, and produce a load largely in excess of that which the horsepower and velocity indicates. Further, wheels which are to be run at differet speeds should be designed for the speed which produces the largest load. The preceding method has been used more particularly to show how the Lewis Formula for horsepower can be used to determine the load on the teeth, and if the load is known, the teeth can be designed accordingly.

Horse Power of Electric Motors.

The horsepower of electric motors is measured similarly; the load being determined by means of a device known as a Prony Brake, which consists of two curved blocks clamped on the motor pulley and provided with thumb screws to regulate the pressure. The lower block is extended with an evenly balanced wood arm of convenient length, in the end of which is fastened a lag screw. The point of the screw pressing on the platform of a scale, registers the load in pounds transmitted from the motor by means of its torque or twisting stress, and the amount of torque equals the number of pounds registered on the scale, multiplied by the length of the lever arm in feet from the centre of pulley to the centre of lag screw. The electrical formula reads, H.P.=

$$\frac{2 \times 3.1416 \times T \times S}{33{,}000}$$

, in which T = torque, and S = revolutions per minute. In measuring the load by this method, we have increased the diameter of the motor pulley to twice the length of the lever arm, or the lever arm is the radius of the circle through which the load is measured, and 3.1416 is multiplied by 2 for this reason. The Lewis and electrical formulae are therefore identically

GEARS AND PULLEYS.

$$D : d :: r : R$$

D = pitch diameter of driver = $\frac{d\,r}{R}$

d = " " " driven = $\frac{D\,R}{r}$

R = revolutions per minute of driver = $\frac{d\,r}{D}$

r = " " " driven = $\frac{D\,R}{d}$

$$N : n :: r : R$$

N = number of teeth in driver = $\frac{n\,r}{R}$

n = " " " driven = $\frac{N\,R}{r}$

R = revolutions per minute of driver = $\frac{n\,r}{N}$

r = " " " driven = $\frac{N\,R}{n}$

the same, although presented in somewhat different form. The electrical formula may be made to read H.P.= 2 × 3.1416 × radius in feet × registered load in lbs. × revs. per min. ÷ 33,000, and the Lewis formula H.P.= 3.1416 × diameter in feet × rev. per minute × load ÷ 33,000.

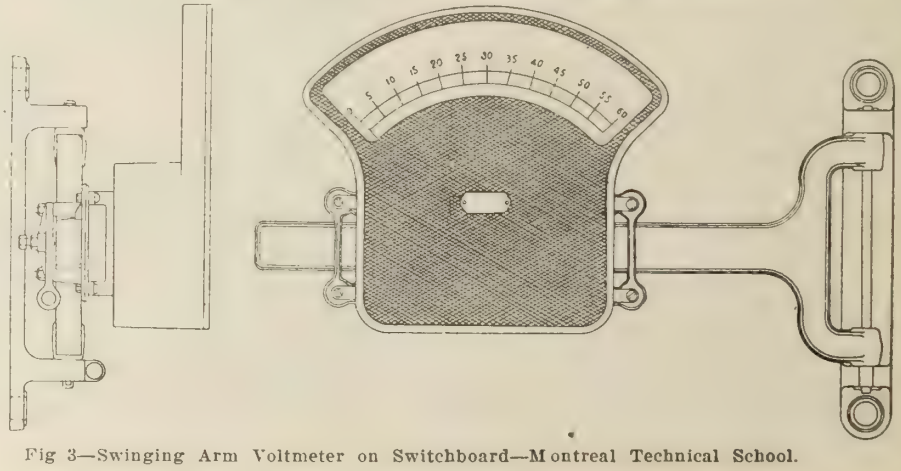

Fig 3—Swinging Arm Voltmeter on Switchboard—Montreal Technical School.

Pitch Diameter and Number of Teeth.

The pitch diameters or number of teeth may also be determined from the foregoing equations. These are derived in each case from the diameters or teeth and speeds. The proportions by which the pitch diameters are calculated, serve equally well for pulleys, when the diameter of pulley is substituted.

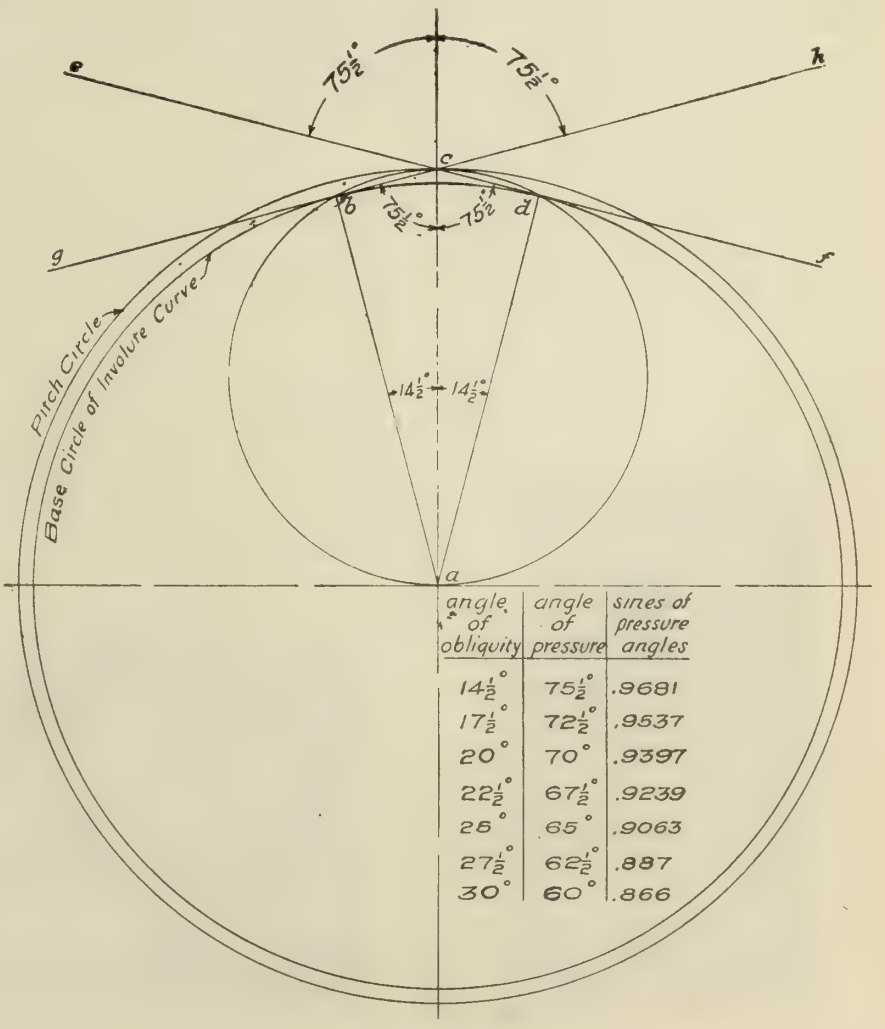
Wheels, which work together continually in one direction, must necessarily wear on one side of the teeth. In order to equalize this wear, due provision should be made to reverse the wheels on their respective shafts. This operation will not be called for, however, if they are reversed by the action of the driving mechanism.

Templets.

An essential feature, in the manufacture of spur gears, is a templet of tooth profiles, by which the cutting and finishing operation may be brought to some degree of accuracy. While templets of only a few teeth are advocated, a full templet of the entire number in a wheel, which can be traced on sheet zinc and cut out, is the only perfect guide by which the inaccuracies of cutting and finishing may be remedied. This is perhaps, a tedious and expensive plan, where only one or a few wheels are required, but when numbers of gears of the same size are to be made, it is the correct thing to do. A wheel, which is perfectly cut and finished, will wear evenly on each tooth, while a gear which is defective, is obliged to wear more on the teeth which are incorrectly formed or defective in spacing. It is therefore safe to say, that if a wheel wears excessively on a few teeth, there are sure to exist defects of some kind in those teeth. One rotary gear cutter can only be perfect for one number of teeth of its diametral pitch, and its profile should be formed with due provision for the finish of that number of teeth. As tooth faces which have been formed by a rotary cutter are utterly unfit for use unless they are filed or otherwise finished, rotary cutters usually have a range of several numbers of teeth whose profiles closely resemble it, and the cutter will cut them equally correct, if a templet is provided while while the teeth are being finished. The finish of the engaging faces of gear teeth is quite as important as the finish of a shaft bearing. Well finished teeth add to the life and efficiency of a well cut wheel, although gears are often made defective in finishing, by reason of the fact that no templet of the teeth is provided.

Tooth Profiles.

Spur gear teeth, in common use, are divided in two classes, and known as double curve and single curve, or cycloidal and involute teeth. The cycloidal or double curve tooth is composed of two curves. The upper curve, or that part of the profile which projects from the pitch circle, is known as part of an epicycloid, and is obtained by the geometrical operation of rolling a generating circle on the outer circumference of the pitch circle. The lower curve is known as part of a hypocycloid, and is obtained by rolling a generating circle in an opposite direction on the inner circumference of the pitch circle. The operation necessary to produce one perfect profile, however, is not by any means unimportant and has led to the adoption of an approximate method, extensively used, and closely resembling the true profile in normal wheels.



The Involute Curve.

The involute curve is obtained by unwinding a string from a cylinder. Involute or single curve teeth are more generally used than cycloidal teeth. The base of the single curve extends below the pitch circle, while the remaining portion of flank, between the fillet at the bottom of tooth and the base circle, radiates with the centre of the wheel.

Fig. 3 contains a diagram by which the diameter of the base circle of the involute curve may be determined graphically, and also calculated. Involute teeth are more commonly distinguished by their angle of obliquity ; this being the oblique angle which the curve assumes with respect to a line through the centre of the wheel, and through the commencing point of the curve. The angle of pressure is at right angles to the angle of obliquity hence the angle of pressure equals 90 degrees minus the angle of obliquity. In Fig. 3 the angle of obliquity is 14½ degrees, being the angle in common use for ordinary wheels. The pressure angle 75½ degrees is defined by the lines e-c-f- and g-c-h, which are each 75½ degrees with the perpendicular line a-c. A circle, tangent to these two lines, is the base circle of the involute curve. One line is usually sufficient, however, in drawing the wheel.

Calculation of Base Circle Diameter.

In order to calculate the diameter of the base circle, we shall apply principles of trigonometry. It will be noticed that a circle has been described on the radius of the pitch circle which intersects the line e-c-f at "d". A line at right an-

angle of obliquity	angle of pressure	sines of pressure angles
14½°	75½°	.9681
17½°	72½°	.9537
20°	70°	.9397
22½°	67½°	.9239
25°	65°	.9063
27½°	62½°	.887
30°	60°	.866

Fig. 3 — Spur Gears.

gles to e-c-f from the centre "a" terminates at "d," which point is also the point of tangency of the base circle, as well as the intersecting point of the semi-circle; therefore the triangle a-d-c is a right angled triangle, since we cannot draw any other in a semi-circle with lines from the extremities of its diameter, to a point on its semi-circumference. This is well defined in the 3rd book of Euclid, proposition 31. The angle at "c" is equal to the opposite angle of pressure 75½ degrees, as defined in the 1st book of Euclid, proposition 15, and the angle at "a" is its complement, or the angle of obliquity 14½ degrees.

The hypotenuse of the triangle a-d-c, is the radius of the pitch circle a-c-, and the radius of the base circle of involute curve is the line a-d, therefore the radius of the pitch circle a-c, multiplied by the sine of pressure angle, or divided by the secant of the angle of obliquity, equals the radius of the base circle a-d. The diameter of the base circle can also be determined in a like manner, multiplying the diameter of the pitch circle by the sine of the pressure angle, or dividing it by the secant of the angle of obliquity. From the preceding, it will be noted, that with every change made in the angle of pressure, a corresponding change effects the triangle in the semi-circle; viz.: the angle at "a" is always the angle of obliquity and its complement is the angle of pressure. In the lower part of Fig. 3 will be found the sines of the pressure angles in general use and with which we may readily determine either the radius or diameter of the base circle of the involute curve without the aid of a protractor.

Applicability of the Chain Drive to Power Transmission

By C. T. R.

The Writer Points Out the Particular Circumstances Which Led to the Introduction of Chain Driving for Power Transmission Purposes, the Conditions Under Which It is Not Possible to Make Use of the System, and Details the Special Features Which Have Contributed to Highly Satisfactory Results in Numerous Installations.

NOW, that electricity is being so largely utilized by manufacturers and power-users in Canada, it is necessary to consider carefully the question of methods of transmission, because of the fact that this governs to a lesser or greater extent, the difference between the cost per horse power charged by the Power Co., and the cost per useful or productive horse power at the machine. Hitherto, the steam, gas or oil engine has provided a margin of power generally sufficient to cover losses in transmission without showing any increase on the power bill; but as power companies charge for the current taken by the motor and not the actual horse power at the machine, then, unless the transmission is efficient and the frictional losses low, hundreds of dollars may be paid each year for something which is not available for production purposes.

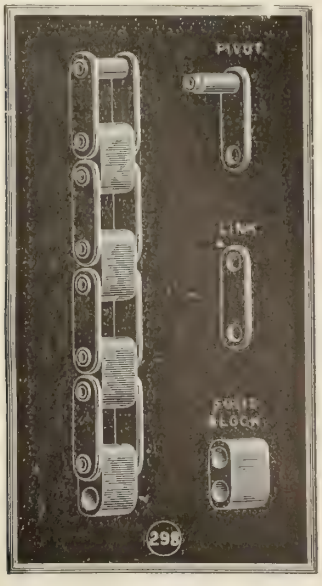


Fig. 3 — Solid Steel Block Chain Used for a Variety of Purposes.

Chain Drive Limitations.

There are many locations and conditions, particularly suited for belts, ropes and gears, and these systems will never be discarded; yet as the system of power transmission by chain has become more widely known, its advantages have been quickly appreciated and its popularity greatly increased among prominent Canadian firms. Chain driving of course has its limitations; for instance where power has to be transmitted at right angles, or where the driving and driven shafts run in opposite directions. This latter instance in itself debars its use on fully half the machine tools in service, and where otherwise it would be applicable. Chains are not affected by moisture, heat or oil; belts and ropes tend to slip under such conditions, with resultant loss of power accompanied by destructive heat. It was, however, in cases where shafts were too far apart for gears and too near for belts or ropes that chains made their debut. Their success in these fields, suggested trials in others.

Some Types of Chain for Power Transmission.

Fig. 1 represents the patent liner silent chain for speeds up to 1,300 ft., and having special provision for lubrication at still higher speeds.

Fig. 3 represents the bush roller chain for speeds ranging from 400 to 900 ft. per minute.

Fig. 4 represents the solid steel block chain for speeds up to 400 ft. per minute.

In each type, the links of the chain are blanked from steel strips of high tensile strength, and the bearing surfaces are of case-hardened steel. Briefly put the patent silent chain is suitable for practically all classes of high speed drive, the roller chain for heavy moderate speed drives as for automobile transmission, and the steel block chain to the variety purposes for which the malleable link chains have hitherto been used. In the present article, attention is directed only to the patent liner silent chain, on

Fig. 1a.

account of its being especially suitable for use in conjunction with electric motors. Figs. 4, 5, 6, 7, 8 and 9 show typical applications. The advantages claimed for the patent liner silent chain are briefly as follows :

Efficiency.

The efficiency is high, and moreover, is constant throughout its life. The principle of the chain is that of tooth gearing, and all possibility of slip is eliminated. Journal friction, i.e., loss of power, is a minimum, as the chain can be run practically slack on the wheels. With belts, considerable tension is frequently necessary, and particularly so with the small pulleys of high speed electric motors.

Durability.

This is largely governed by the conditions of each particular drive. We understand that there were drives installed in Canada 5 years ago, and still in service, which originally replaced other forms of transmission that could not stand the severity of the load and continuous service. These drives have been running regularly night and day, and apart from receiving lubrication, have not given any trouble. Other drives have been in regular service upwards of seven years, and with improvements in design and manufacture since then, even better results may be expected. Chains wear of course, after continuous service, but for the reason that they automatically rise on the wheel teeth as the pitch increases, the efficiency keeps constant.

Quiet Running.

In many instances, the gear makes no greater sound than a medium sized belt. It is impossible to have metallic pieces moving with absolute silence, and its degree is affected by the speed of the chain and the number of teeth in the sprockets. Noise is only produced when the chain speed is excessive, and when the number of teeth becomes very low.

Design.

The success of a chain drive is of course essentially a function of the design and material of construction. In a well designed gear, the action of the chain entering the wheel is purely a rolling one, see Fig. Ia, and except on wheels with exceptionally few teeth, sliding and hammering may be practically eliminated. The strength of a chain depends more upon the bearing area (see fig. 1) of the studs connecting the links, than any other feature, and this should be ample with the load distributed. The material of the wheels should be influenced by the ratio of the speeds between the driver and driven shafts, and should be such that the wear on each wheel is the same. The life is considerably shortened if the wear on the wheels is not proportional.

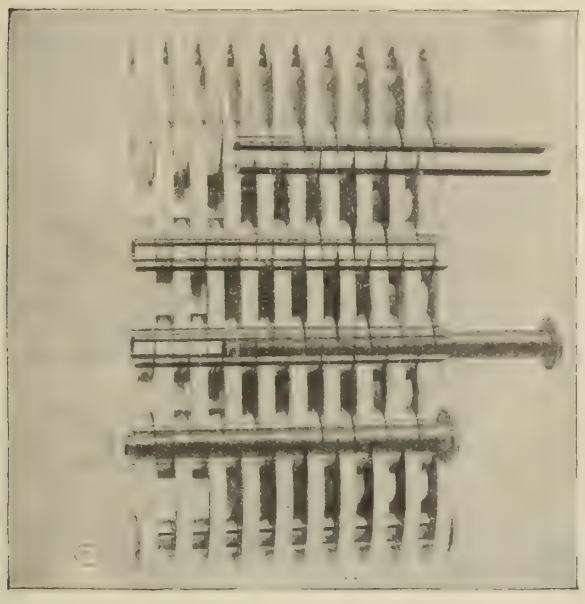

Fig. 1—Hans Renold Patent Liner Silent Chain.

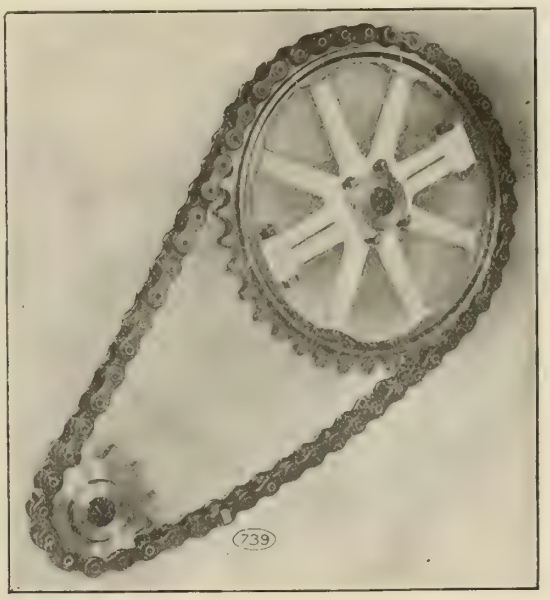

Fig. 2—Bush Roller Chain Drive for Heavy Loads and Moderate Speed.

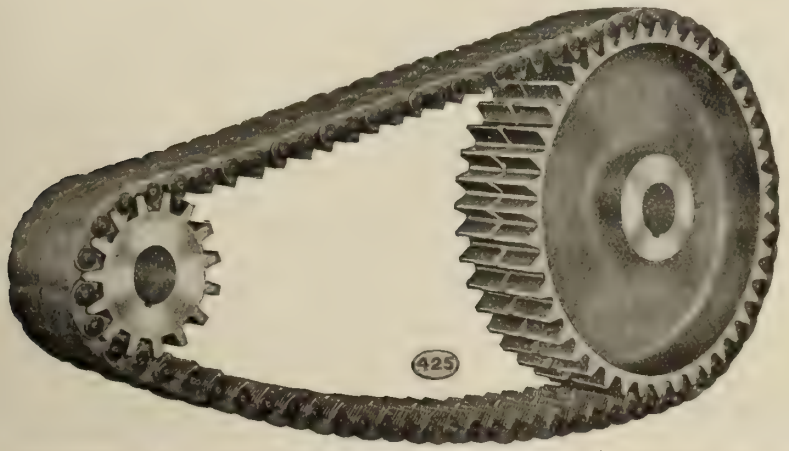

Fig. 4—A Typical 65 H.P. Silent Chain Drive. Wheels 15 and 65 T. Diameters, 7.5" x 31.25". Chain, 1.5" Pitch, 6" wide. Shaft centres, 5 feet.

Compactness.

This is probably one of the most important advantages chain transmission offers over belts or ropes, and it secures admission for the system into an unlimited field of application. The chain sprockets are approximately one half the size of belt pulleys of the same capacity, and they may be placed quite close together, thus economizing in space, and often providing a more convenient and satisfactory arrangement of machines. Again, the width of the chain is usually about one third the width of a belt for the same power.

To many, the first cost of a chain drive is an obstruction ; this being about 50 per cent. for small powers, and as

low as 35 per cent. for large powers, higher than a belt drive of equal capacity. It should be borne in mind, however, that higher efficiency, saving in power and increased production, mean more satisfactory transmission, at low cost. There are several hundred chain drives in use in Canada, a large majority of which are transmitting upwards of 200 h.p., with centres as short as six feet. Undoubtedly, as the system becomes more widely known and its advantages realized in actual service, adaptation will become much more general.

For the illustrations shown in this article we are indebted to Jones & Glassco, Montreal, the Canadian Agents for Hans Renold, Ltd., Manufacturers of chain driving gear, of Manchester, England.

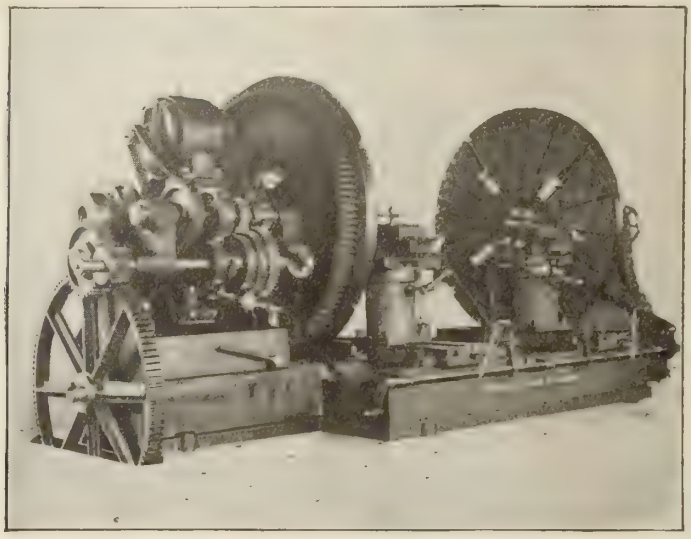

Fig. 7 — Lathe Drive from Motor by Silent Chain.

TO PREVENT STRIKES IN BRITAIN

The Labor Disputes Bill, which has been prepared by Will Crooks, M.P., and has received the approval of all political parties, proposes that wherever a dispute exists between an employer and any of his employes (numbering ten or more), and the parties are unable to adjust it, either of them may apply to the Board of Trade for the appointment of a board of conciliation and agreement to which the dispute may be referred.

Conciliation Board and Its Powers.

Each board is to consist of three members, one selected by either party, and the third (who is to act as chairman) on the recommendations of the members so chosen. "In every case where a dispute is duly referred to a board, it shall be the duty of the board to endeavor to bring about a settlement," and to this end it is empowered not only to make expeditious inquiry into all the matters at issue, but to put witnesses on oath and to call for the production of all necessary books, papers, and documents, as well as to enter at any time any building, mine, or factory included in its inquiry, and conduct any inquisition or interrogation it pleases. These ample powers come into operation whenever a board is appointed.

It is to be enacted that "it shall be unlawful for any employer to declare or to cause a lock-out, or for any employe to go out on strike, on account of any dispute, prior to or during a reference of such dispute to a board of conciliation and investigation under the provisions of this Act."

Lock-out and Strike Penalties.

Delinquent employes are to be liable to a fine of not less than $10, and not more than $50 per day. For employers who illegally declare a lock-out the penalty may be the minimum of $50 or the maximum of $1,000 per day. Those who incite either employers or employed to a breach of the law will be liable to a fine of not less than $50 and not more than $1,000. The parties do not regain their liberty to strike or lock-out until the subject in dispute has been dealt with—and not even then, it would appear, if they have bound themselves in writing to accept the settlement that the board may recommend; for in such circumstances the recommendation is to become legally enforceable.

APPRENTICESHIP AND THE UNEMPLOYED.

Much help is being given in solving the problem of the unemployed in England, by the National Institute of Apprenticeship. The majority of the unemployed are out of work because they are unskilled laborers, and the great number of unskilled is largely due to the diminution of apprenticeships. This Institution was founded six years ago "in order that boys and girls should start life not only with a liberal education and training given in the schools, but also with a practical training which was to be had in the workshop." Since it began work a large number of boys have been trained, and applicants

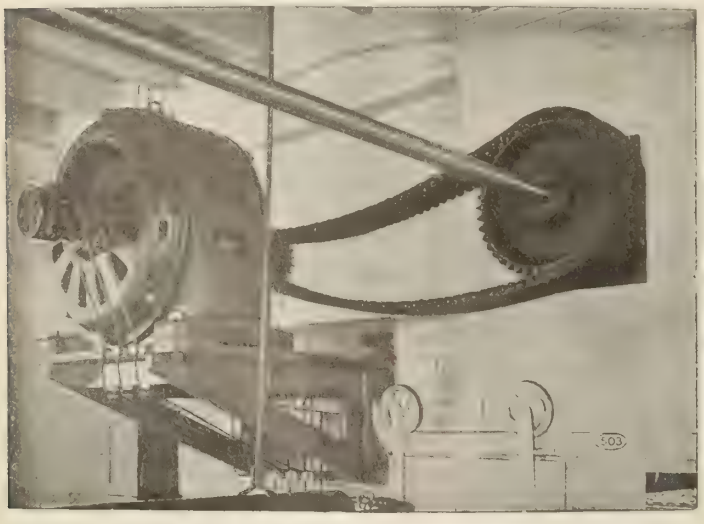

Fig. 5 — Typical Silent Chain Drive from Motor to Lineshafi.

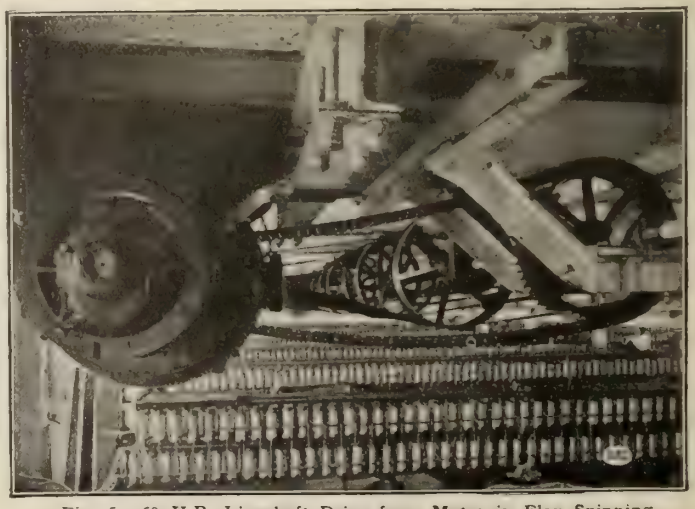

Fig. 6 — 60 H.P. Lineshaft Drive from Motor in Flax Spinning Mill, by Silent Chain.

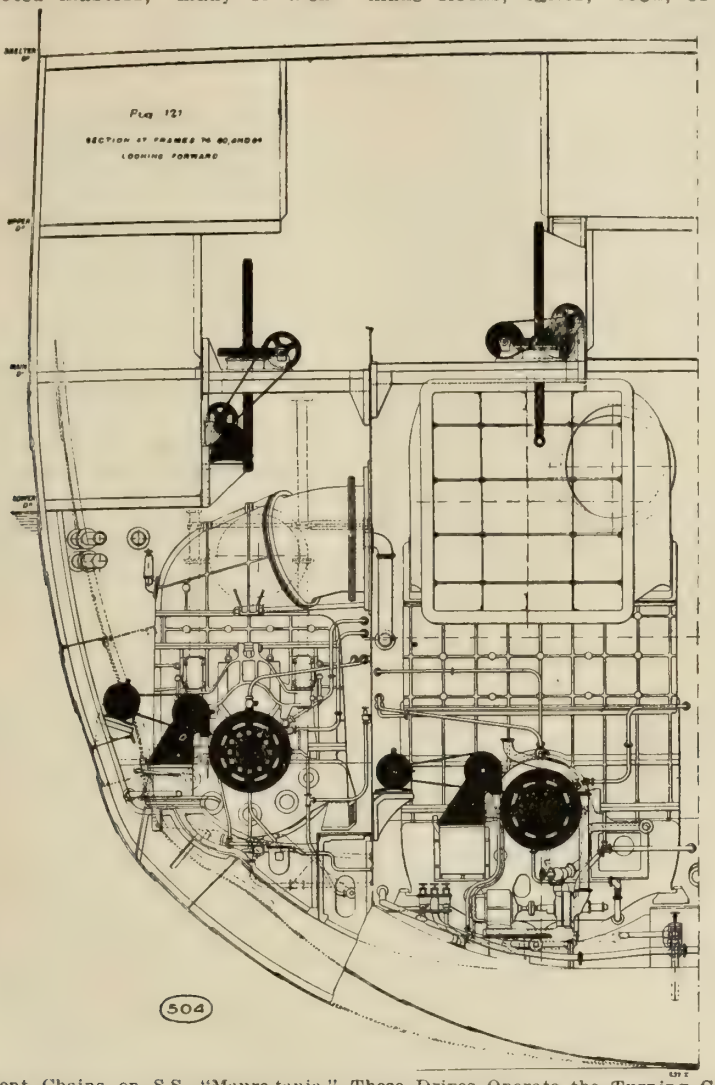
for places now exceed forty a week.

On the registers of the institution there are the names of nearly 300 carefully selected masters, many of them ranking among the most important in their respective trades, who have taken or agreed to take apprentices for the institution. The only qualification required for an applicant is his, or her, respectability and fitness for the selected trade. No other questions are asked, and no other restrictions imposed. The institute supervises the apprenticeship so as to ensure, as far as possible, that the apprentices are properly taught their trades and do their duty to their masters.



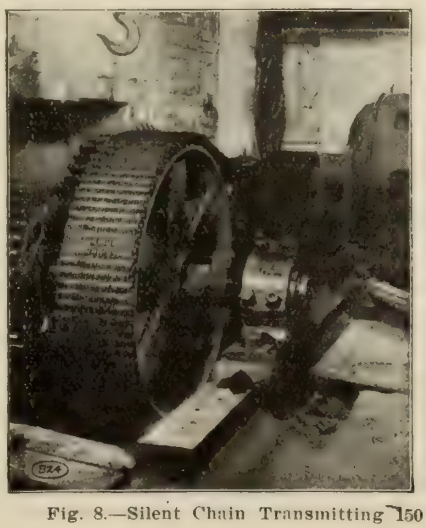


Fig. 9—Silent Chains on S.S. "Maure tania." These Drives Operate the Turning Gears for the Propeller Shafts and Turbines Respectiv ely.

A Trade the Best Legacy.

A man who teaches his boy a trade provides more certainly for his future than if he leaves him a large property, but without knowing how to turn his hand to useful employment. The ancient Hebrews had a saying: "He who does not teach his boy a trade, leaves him to a thief." It is almost as true to-day as it was in any period of history. A university diploma is by no means an insurance against lack of work. a man who can fashion a horseshoe, make furniture, mould, engrave, varnish, make clocks, tailor, cook, or build a house, is not long out of employment. If he can do either of these things well, and is willing to work, he need never walk the streets seeking for work and not find it.

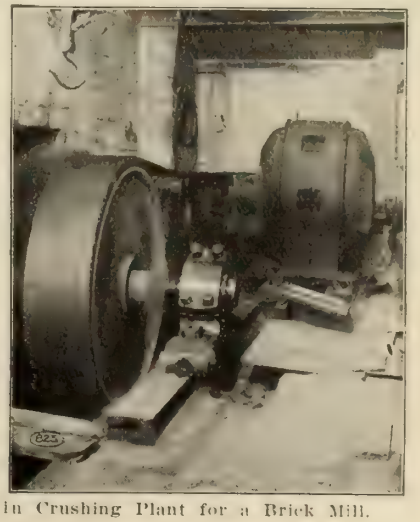

Fig. 8.—Silent Chain Transmitting 150 H.P. in Crushing Plant for a Brick Mill.

MEETING OF THE FOUNDRY EXHIBITION COMPANY.

A meeting of the board of directors of the Foundry and Machine Exhibition Co., was held in Buffalo, Friday and Saturday, Sept. 15 and 16, for the purpose of investigating the exhibition facilities afforded by the large halls in that city. While no definite arrangements have been made, it is altogether probable that a hall suitable for the use of the Exhibition Company will be obtained, the final decision having been left with the executive committee. The American Foundrymen's Association and the Associated Foundry Foremen were also represented, and preliminary plans were discussed for the annual foundrymen's meeting which will be held in Buffalo next year.

As usual, the exhibition feature of these conventions is usually a financial success, and Pittsburg was no exception. The directors of the Foundry and Machine Exhibition Co., declared a 20 per cent. dividend, payable immediately to all exhibitors who were represented at two successive exhibits. To those who displayed their product in Pittsburg for the first time, this 20 per cent. dividend will be held in reserve and if they exhibit in Buffalo, this dividend will be returned to them.

Officers for the ensuing year were elected as follows: President H. R. Atwater, Osborn Mfg, Co., Cleveland; vice president, R. S. Buch, A. Buch Sons, Co., Elizabethtown, Pa.; secretary, C. E. Hoyt, Lewis Institute, Chicago; treasurer, J. S. McCormick, J. S. McCormick Co., Pittsburg. Executive committee, F. N. Perkins, Arcade Mfg. Co., Freeport, Ill.; E. H. Mumford, Mumford Molding Machine Co., Plainfield, N.J., and R. S. Buch, trustees, three years, Henry A. Pridmore, Henry E. Pridmore, Chicago; J. W. Campbell, Cleveland Wire Spring Co., Cleveland, and R. S. Buch.

TIRE LIFTING GRIPS

By R. N. Saunders, Montreal.

THE accompanying cuts show a useful form of lifting tackle, which has been found to greatly facilitate the rapid handling of locomotive and coach wheel tires between the boring mill and the shop floor. Fig. 1 shows the construc-

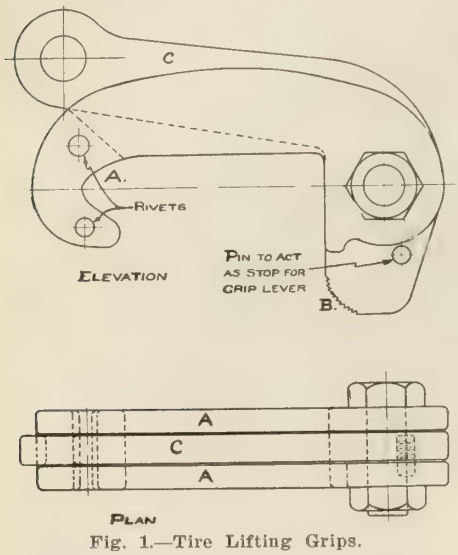

Fig. 1.—Tire Lifting Grips.

tion of the grip which consists of a bent lever, C, having its lower edge serrated and hardened, as shown at B. This lever is fulcrumed between two plates, A, shaped at one end to fit over the flange of the tire. A distance piece is riveted between the plates at this end to prevent them spreading. The fulcrum for lever C consists of a $\frac{7}{8}$ inch bolt. The small pin or stud shown in C, is intended to prevent A from falling into line with the lower arm of C, when the grip is lifted from the floor preparatory to being placed on the tire. It has been

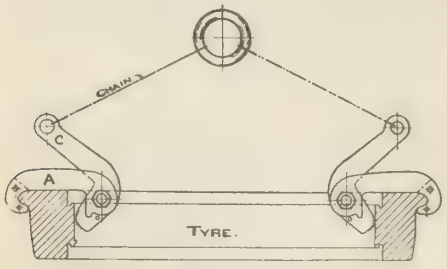

Fig. 2 -Tire Lifting Grips.

found of little practical value, however, and usually gets broken off in a short time.

Fig. 2 shows a pair of grips completed with their chains and ring. It will be seen that they are only adapted for lifting a tire in this one position—that is, with the flange uppermost.

Editor's Note.—We invite sketches and descriptions of a grip suitable for lifting a tire in the opposite position to that shown in Fig. 2, i.e., with the flange downwards. All designs must have been given a successful practical trial. Any design accepted will be paid for at our usual rates.

A PNEUMATIC FEED FOR AIR DRILLS.

By F. G. Goddard, Montreal.

The device herein described was designed for drilling locomotive saddle-bolt holes in the erecting shop after the boiler is in place, at as high a rate of speed as could be obtained in the machine shop on a radial drill. A small air cylinder fitted with piston, guide-bars and crosshead is attached to an air motor by means of a coupling, Fig. 2, screwed into the motor in place of the usual feed screw. This coupling is also attached to the end of the guide-bars in such a way that the motor is free to rotate on its axis, this condition being necessary to relieve the guide-bars of all twisting strain when drilling.

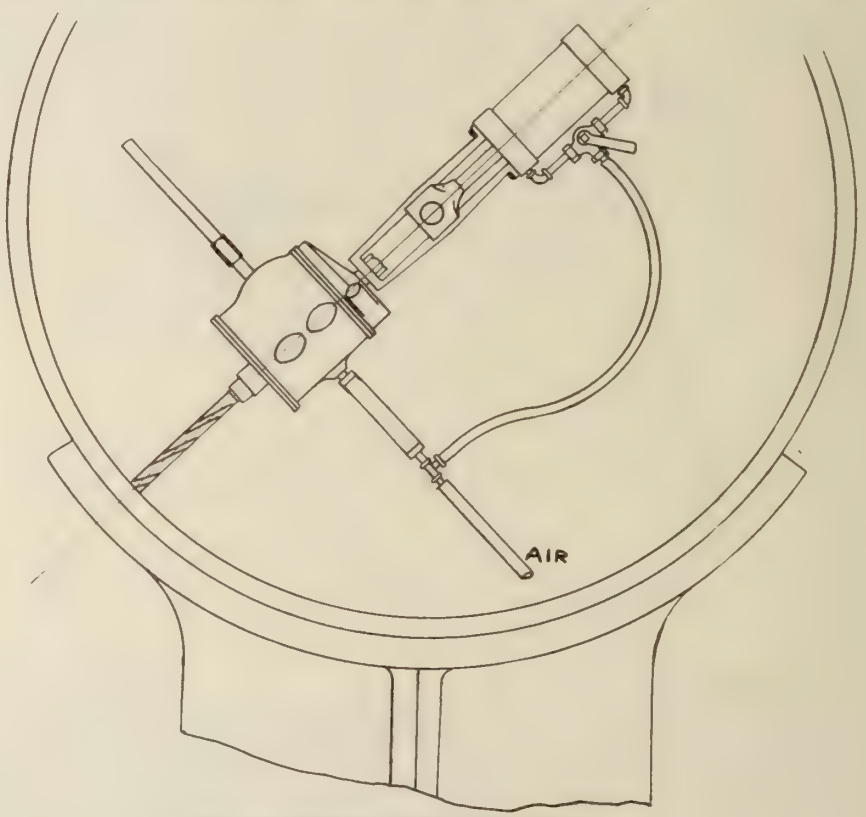

Fig. 1.—Pneumatic Feed for Air Drill.

When in operation, a 2 inch round bar or pipe of extra heavy section is rigidly stayed in the centre of the smokebox by means of two spiders, Fig. 3 ; the motor and cylinder being suspended between the spiders on the bar which passes through a 2 inch hole in the crosshead. The air supply to the cylinder is tapped off the motor supply by means of a tee and short length of hose to a three-way cock on the cylinder. It can be manipulated to give exactly the requisite amount of pressure to feed the drill, or on being reversed, backs the drill out of the hole. As the crosshead and piston are attached to the 2 inch bar, they remain stationary when air is applied ; but the cylinder moves either up or down, and with it the guidebars and air motor. It will be noticed that every hole thus drilled is perfectly radial from centre of the smokebox. The apparatus was so designed that drills of average length could be used in smokeboxes of the smallest diameter ; consequently in those of larger diameter drill sockets or extensions must be used to make up the length, so that the point of the drill swings 1 or 2 inches clear of the inside of the smokebox when in the back-up position.

When drilling, the motor should be at its full speed before any feeding pressure

is applied, and a chalk mark should be put on the drill to show when it is about to point through the outside of the saddle, at which juncture the air feed must be shut off and the drill al-

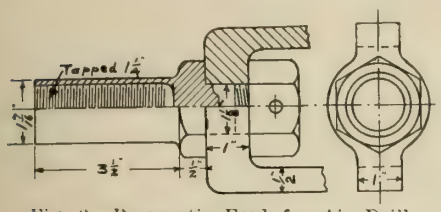

Fig. 2.—Pneumatic Feed for Air Drill.

lowed to go through by its own weight, otherwise it is liable to jam or break the point of the drill. If properly handled and using high speed drills, saddle-bolt holes can be drilled in this manner at the rate of one every 1½ to 2 minutes, and the time required to change from one hole to another is but a few seconds. The device was originally intended for use in the case of new cylinders being applied to a repair engine, but it was afterwards found that a great saving in time could be effected in the case of new engines, by punching the holes in the smokebox, before rolling, and then drilling the saddle as described after the boiler is in place on the cylinders. It has also been used to advantage for drilling out old saddle-bolts when stripping boilers.

The correct size of cylinder was only arrived at after one or two trials. Finally, a diameter of 5 inches, with an air

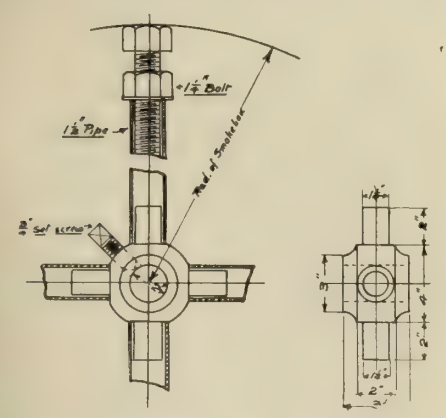

Fig. 3.—Pneumatic Feed for Air Drill.

pressure of 70 to 80 pounds was found to give a fairly heavy feed to high speed drills up to 1⅛ inches diameter. The stroke of the cylinder is 8 inches.

CUTTING KEYSEATS ON A LATHE.

By H. E. Fozard, Ottawa.

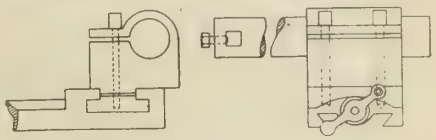
Time may often be saved when keyseats are required to be cut on a job already in the lathe. The saving consists in obviating the necessity to remove the work from the chuck and the consequent setting-up on another machine. Ablute accuracy of performance is at the same time secured. The following example describes the method and apparatus involved.

Assuming that a keyseat ¼ inch wide is to be cut in a hole 1 inch diameter. Take a piece of ¼ inch square tool steel, grind clearance as for cutting-off tool and place in boring bar, with cutting edge at right angles to lathe bed. Set the centre of the tool level with centre of the hole to be keyseated and wind saddle backward and forward, feeding to the required depth with the cross slide rest. By this means, it is possible to cut keyseats up to ½ inch wide. When cutting soft steel and cast iron, it is necessary with the larger size keyseats to put a small tool through first, afterwards finishing with a tool the required width.

Knurled Burnishing Tool.

I may say that the actual cutting time compares very favorably with that taken on a shaping machine.

NOVEL METHOD OF FLUTING SMALL BURNISHING TOOLS.



By Chas. Hattenberger, Buffalo.

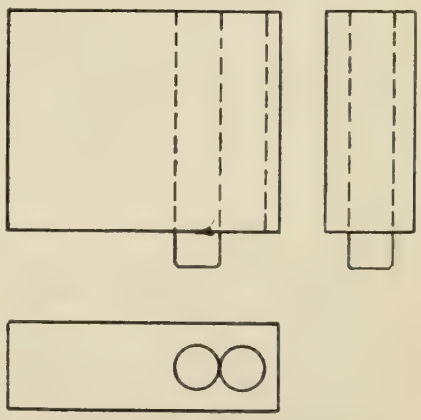
The firm with whom I was employed used large numbers of small barrel cams. The cam-way was about 5-16-inch deep. Owing to the extreme accuracy required, the usual method of machining the cam-way was to mill it .00005-inch under size, and then finish by burnishing. It was customary to make the burnishing tool of high speed steel; turning the blank .010-inch over size and then milling flutes about 1-32-inch apart. The tool was afterwards hardened and ground. Because of the quantity used, this milling operation proved rather expensive, therefore, to cut down cost, we adopted the following plan. We turned the burnishing portion of the tool to the exact size and then knurled it. The knurling increased the diameter by about .010-inch. In grinding to size, small right and left hand flutes were thereby formed. This method of fluting made a smooth job and reduced the expense very materially.

DRILLING JIGS FOR IRREGULAR HOLES.

By A.D.C., Hamilton.

When drilling out blanking dies or any other holes of irregular shape, much time can be saved by the use of the little jig here shown. Ordinarily when drilling out such dies a lot of time is lost, in so locating successive holes that they will just break into the one previously drilled. This trouble is overcome by this jig which consists of a piece of machinery steel in which a hole is drilled equal to the size of drill for which the jig is to be used. Into this first hole there is driven a piece of hardened steel which is allowed to project a short distance beyond the bottom as shown. A second hole, a shade larger, is now drill-

Boring Tool for the lathe.



ed so as to just touch the first hole, and the jig is complete.

To use it, drill one hole in your die in the usual way; then insert the projection on the jig in the hole so drilled and bring your drill down into the second hole in the jig. Simple, isn't it? The drawing shows a jig for a ¼ inch drill.

BORING TOOL FOR THE LATHE.

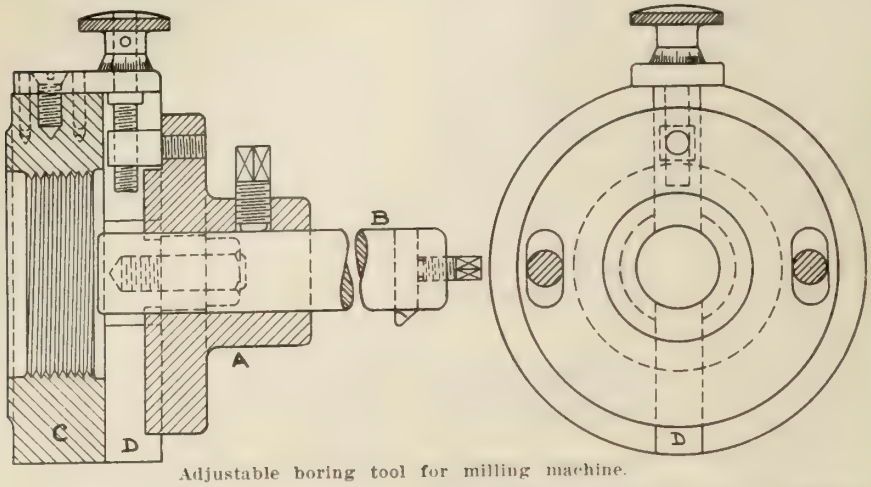
By W. B. Cook, Medicine Hat.

In our shop we use the boring and threading device here illustrated and find it a useful attachment for the engine lathe. As may be seen from the sketch, it is simple and easily made. The ordinary tool post is removed from the slide rest and the boring tool substituted for it. The two cap screws pass through the body, and are tapped into the base plate, clamping the boring bar

Drilling Jig for irregular holes.

and the tool holder itself at one operation.

The cap screw heads are square, and of the same size as the tool post screw head, so that one wrench fits all. The boring bar at one end is slotted through at right angles to the axis as shown. If the other end is slotted through at an angle of about 40 degrees and the bar cut off parallel to the slot, the tool will be able to handle most inside work. The cutter is of course set by turning the bar sightly in its holder.



Such a tool as this is a useful addition to the small general shop.

ADJUSTABLE BORING TOOL FOR MILLING MACHINE.

By A.D.C., Hamilton.

In this tool, casting A carries the boring bar B, and slides across the face of casting C. A is guided in a straight line by means of a tongue which fits into the grove D, running across the centre line of casting C. The two studs in C, working in elongated holes in A, lock the boring bar after adjustment has been made by means of the micrometer screw. Casting C is screwed to fit the spindle of the milling machine.

This little attachment is easily made and has proved extremely useful in the tool room.

Adjustable boring tool for milling machine.

AN EXPANDING BORING HEAD.

By W.H.J., Toronto.

A simple form of expanding boring head is herewith illustrated. It is an invaluable tool in shops where a large amount of fine work is done. Referring to Fig. 1, it will be seen that a slot is milled in the tool body, which is of machinery steel. The two cutters are inserted in the slot and after they have been adjusted to size, the ring is screwed down, locking them securely in position. The ring is ground true on the back and hardened.

Adjustment is effected by means of the hardened steel adjusting screw, the point of which engages with the bevelled edges of the cutters and pushes them apart as it advances. The drawing shows a tool for boring any diameter from 3¼ inches to 3⅝ inches. Fig 2 shows the arbor for driving the boring head. This presents no special features, except that the driving tongue is not solid with the arbor, but is milled on a loose collar which is afterwards shrunk on and pinned. This method of construction reduces the cost considerably.

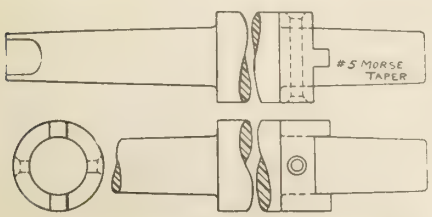


Fig. 2 –Expanding boring head.

FLOATING SOCKET FOR A FINISHING REAMER.

By L.E., Hamilton.

The sketch of this device needs little explanation as the construction is clearly shown. The socket floats on the points of four screws, allowing the reamer to adjust itself to the work. The holes in the ball head are made about 1-16 inch larger in diameter than the points of the screws. The sketch shows a socket for a taper shank reamer, but of course the idea is applicable to any style of shank.

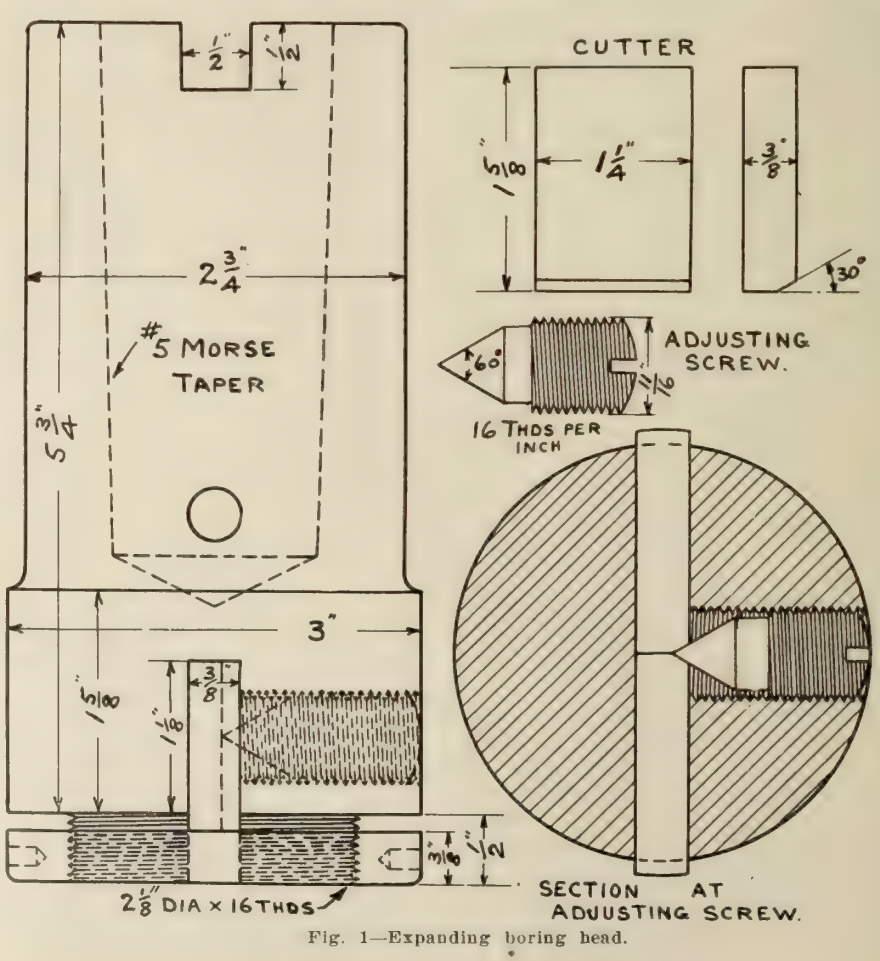
MALLET LOCOMOTIVES ON THE C. P. R.

The Mallet articulated compound locomotives built during the present summer by the C.P.R. at their Montreal shops, are showing excellent results in service. They are stationed at Field, B.C., and work east from there to Stephen. Another will be turned out in October, differing from its predecessors, in being a simple engine with four high pressure cylinders, and making the sixth "Mallet" to be put into service by the company. Its performance will be watched with interest.

BOILING POINTS OF METAL.

In a paper presented at a meeting of the Faraday Society, London, Eng., H. Greenwood gave the boiling points of various metals at atmospheric pressure as follows:

	Deg. Cent.	Deg. Fahr.
Antimony	1,440	2,624
Bismuth	1,420	2,558
Copper	2,310	4,190
Lead	1,525	2,777
Magnesium	1,120	2,048
Silver	1,925	3,497
Tin	2,275	4,127
Aluminum	1,800	3,252
Chromium	2,200	3,992
Iron	2,450	4,442
Manganese	1,900	3,452



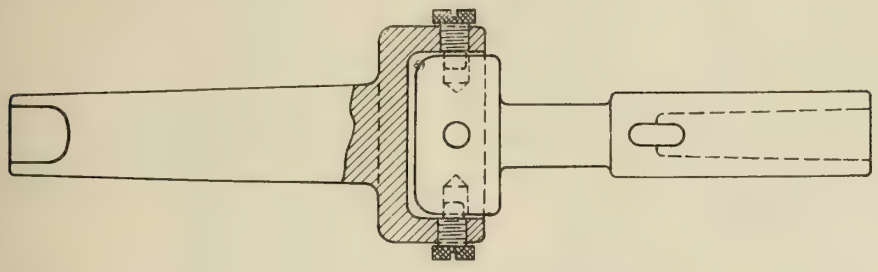


Fig. 1—Expanding boring head.

J. S. CONRADI, MANAGER THE POLSON IRON WORKS.

CONCURRENT with the announcement of the intended extension to the plant of the Polson Iron Works, the active management of the present plant and of the proposed works has passed into the hands of Mr. J. S. Conradi, late of London, England, whose record in marine engineering and shipbuilding, and management of industrial enterprises is bound to affect favorably the future of this old established plant.

Floating Socket for a Finishing Reamer.

Mr. Conradi was born at Glasgow, forty one years ago, and commenced his engineering career in the workshops of the late firm of Maudslay, Son & Field, of Westminster, who were probably amongst the oldest established and most famous engineers and boilermakers of their day. Besides repeatedly adding to their reputation as marine engineers by supplying the propelling machinery for a large number of battleships and cruisers for the British Admiralty, many of the mills in the Old Country are to-day running with engines built by them almost a century ago, and constituting a record which stands out at the present time, a monument to their skill as engine builders.

Having attained with this firm a thorough grounding in the practical details of engine and boiler building, Mr. Conradi, in order to gain experience in the running of marine engines, and handling and care of boilers under actual working conditions, joined the Ross Line of Steamships chartered by the New Zealand Shipping Co., trading to Australia, South America, the Gulf of Mexico and Canada, and during this service, amongst the other more or less exciting experiences of a sea-going engineer, he with others had to cope with a cargo of cotton afire in mid-ocean on two occasions, and to participate in a wreck experience on the coast of Florida.

Gaining four years valuable experience in this way, and obtaining Board of Trade certificates, Mr. Conradi joined the John I. Thornycroft Co., of Chiswick, Southampton and Basingstoke, the most progressive shipbuilders and engineers at that time in the world, and pioneers in the steel shipbuilding industry. Mr. Conradi remained with them for fourteen years, and besides acting as superintendent and manager for six years, was responsible for the speed and steam trials of many speed-record-breaking vessels built under his supervision. Amongst others might be mentioned, H.M.S. "Speedy," the first war vessel fitted with water tube boilers, and which attained what was at the time, the unprecedented speed of 21 knots an hour.

He was also directly connected with the building by this noted firm, of the first destroyers for the British Admiralty, their astonishing speed attracting the attention of many foreign governments—Germany, Italy, Japan, Sweden and others placing orders later, for similar vessels. The various classes of this type, ranging in speed from 27 to 35 knots per hour, held speed records in each instance. The most interesting of the many vessels built under his supervision are closely connected with historic events which will live long in the memory of the people of the British Empire. We refer to the stern wheel steamers built for the Nile expedition, which did such excellent service during the recapture of Khartoum under the command of Viscount Kitchener, and "Shamrock II," challenger for the America Cup, built for Sir Thomas Lipton. It will be remembered that the late King Edward nearly lost his life, when this yacht was struck by a squall and dismasted, owing to the fore-stay parting, while on a trial spin in the Solent.

Mr. Conradi was among the first in England to appreciate and adopt pneumatic tools to the construction of marine boilers. Illustrations of these tools and of his attachment for expanding the tubes in the lower drums are still being exhibited by the makers. The first steam turbine built and installed in a war vessel, became prominent during his connection with the Thornycrofts. Further, Mr. Conradi has had a good deal to do with the design and construction of internal combustion engines, and it was largely owing to the rapid advance made by this type of engine that he was led to consider the advisability of studying manufacturing conditions from a commercial as well as a practical standpoint, with a view to the reduction of production costs, and to the inauguration and adoption of methods, the success of which when put into practice, brought him into particular prominence in engineering circles in England, and resulted in the Vickers Co. procuring his services some five years ago, to carry out the re-organization of their London factories. The Vickers Co. are of world-wide repute, and as general manager and superintendent of their plants situated at Erith, Crayford and Dartford, Mr. Conradi was connected with one of the largest manufacturers of ordnance, ammunition, rifles and motor cars in England and perhaps in the world. He was elected a member of the Institute of Mechanical Engineers in 1892.

That Mr. Conradi's experience should be of value in this country goes without saying, and we think the Polson Iron Works are to be congratulated on having secured his services.

READER, WHAT DO YOU KNOW?

Among readers of Canadian Machinery there is a clearly defined sincerity of desire to know how each overcomes the daily tasks of the machine, pattern and blacksmith shops, the foundry and boiler shops. It is believed that your methods and devices, while good, may be improved, and thereby made more valuable if you publish them, so that other brains may work on them. We will provide the setting and pay you for the material. When your fellow tradesman puts the superstructure on your foundation, we pay him and pass the "kink" on to you, free. Get into the game.

In matters industrial, the path of peace and profit lies along lines which are truly educational.

New York still leads in water power development, with 885,862 horse-power. California is second and Maine third.

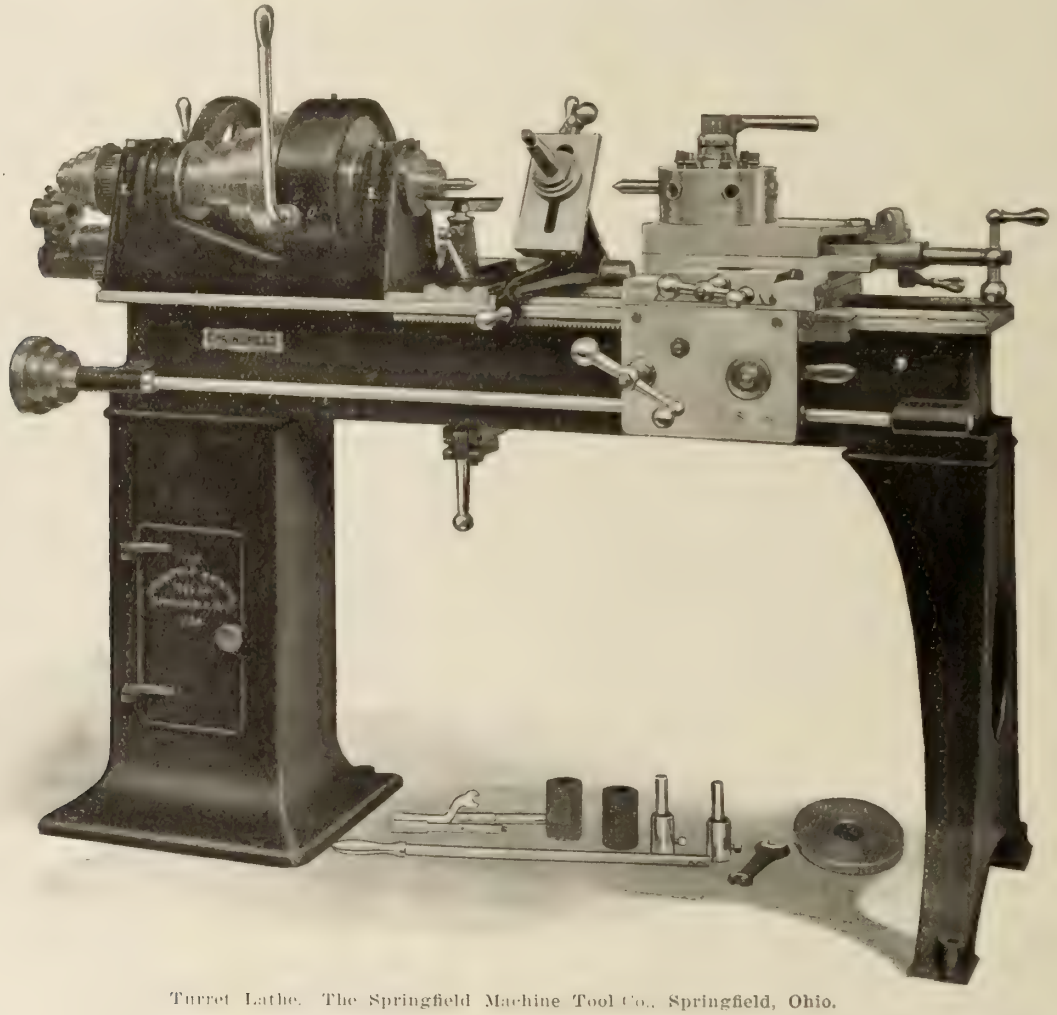
A decline in business permits sifting out the employes, the setting-up of new standards of efficiency and performance, the appraisal of the value of each individual workmen, the readjustment of operating costs and the curtailment of waste, all of which in their previous practice under full pressure, may have contributed more or less to the consumer's burden.

Such a contingency, is preferable to a slaughter of labor, or a stoppage in development and consequently waste of natural resources.

DEVELOPMENTS IN MACHINERY

A Record of New and Improved Machinery Tending Towards Higher Quality and Economical Production in the Machine Shop, Blacksmith Shop or Planing Mill.

A NEW TURRET LATHE.



THE latest product of the Springfield Machine Tool Co., Springfield, Ohio, is a 15 inch by 5 feet cabinet turret lathe, which we herewith illustrate. It contains several new features and improvements, all of which have been introduced with a view to increasing the speed with which work may be handled. Thus, the turret is so designed that one slight backward movement of the blade loosens the turret and at the same time withdraws the locking pin ; a slight forward movement then produces the partial revolution of the turret for the next tool, and simultaneously locks and tightens it, the entire operation being done in a second or so by one hand.

The lathe is back geared, and has a four step cone pulley of large diameter. The spindle is of high grade steel and runs in phosphor bronze bearings. There is an automatic engine feed to the turret, with three changes, which may be reversed by the handle at the left hand side of the apron. Further, there is a longitudinal movement of the turret by either a lever or screw. The top slide of turret rests upon a lower slide having a right angle movement, hand-operated by means of a screw in front of the machine. This allows a large range for facing off work held in a chuck. When using this hand set-over, the holes in the turret can always be brought central again with the spindle by a positive stop. This latter can be quickly removed when tools are to be used back of the spindle centre. The slide has an additional cross movement operated by a supplementary taper slide ; the taper being derived from a bar between the ways of the bed, set by a graduated index to obtain any taper up to 4 inches per foot, thus obviating the necessity of setting over the headstock for taper boring or turning. With this taper attachment work can be faced off square when the job is completed, without any change.

When used for straight work, the taper side is locked to the saddle by a taper pin of tool steel, having a square head for its ready removal.

The machine rests on one cabinet and one plain leg, the former being fitted with shelving for the reception of tools, chucks, etc.

The lathe is driven by a 2 inch belt and its weight with a 5 feet bed is 1,535 pounds.

Turret Lathe. The Springfield Machine Tool Co., Springfield, Ohio.

BALL BEARING JOURNAL JACK.

AMONG late developments in lifting jacks, one which will be of interest to railroad and street railway officials, is an improved ball bearing journal jack recently placed upon the market. It is designed to facilitate the rapid and convenient removal or replacement of journal brasses in freight cars, passenger and Pullman coaches and is especially adapted to railroad service where short, light and powerful jacks are required. Notwithstanding its low cost, there is provided a positive stop which absolutely prevents raising the lifting bar out of the jack. Another important feature is the adjustable wheelholding device designed to hold down the wheel when operating. This device is very essential under many conditions, and may be

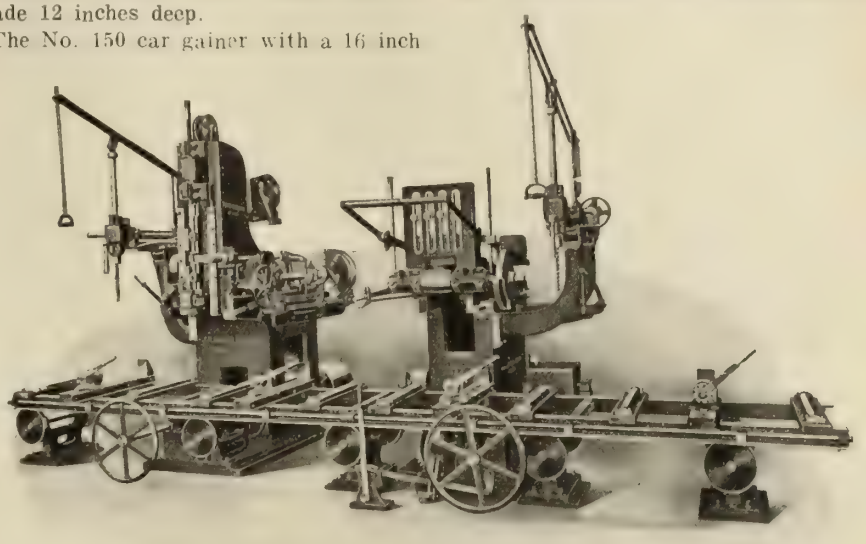
easily detached when not required. The two features just described are also strong factors when considering safety of operation

All gears are forged with machine cut teeth; and, due to its scientific construction, the jack is light in weight and easily handled. The construction suggests ease of operation, as the load is raised only on the downward and most convenient stroke of the lever.

The Duff Mfg. Co., Pittsburg, Pa., are the makers of this tool.

AN EFFICIENCY COMBINATION.

SINCE Mr. Brandeis made his famous "Efficiency Declaration" before the Inter-State Commerce Commission, this word has been much used in all industrial lines but more especially in the railway service. "Efficiency" is generally paraded as something new. The fact remains, however, that machinery builders have for years been designing tools for no other reason than that they would be of a higher efficiency, or in other words, do better and quicker work than the older styles. When it was seen that certain types of tools had reached their highest individual development, manufacturers began to combine one or more separate tools. Pioneers in this work of development in wood-working tools for use in the car shop is the J. A. Fay & Egan Co., of Cincinnati, Ohio. One of their combination productions is illustrated herewith. It is known as the Fay & Egan Combination No. 214 Vertical Hollow Chisel Mortiser and No. 150 Automatic Car Gaining Machine, with boring attachments.

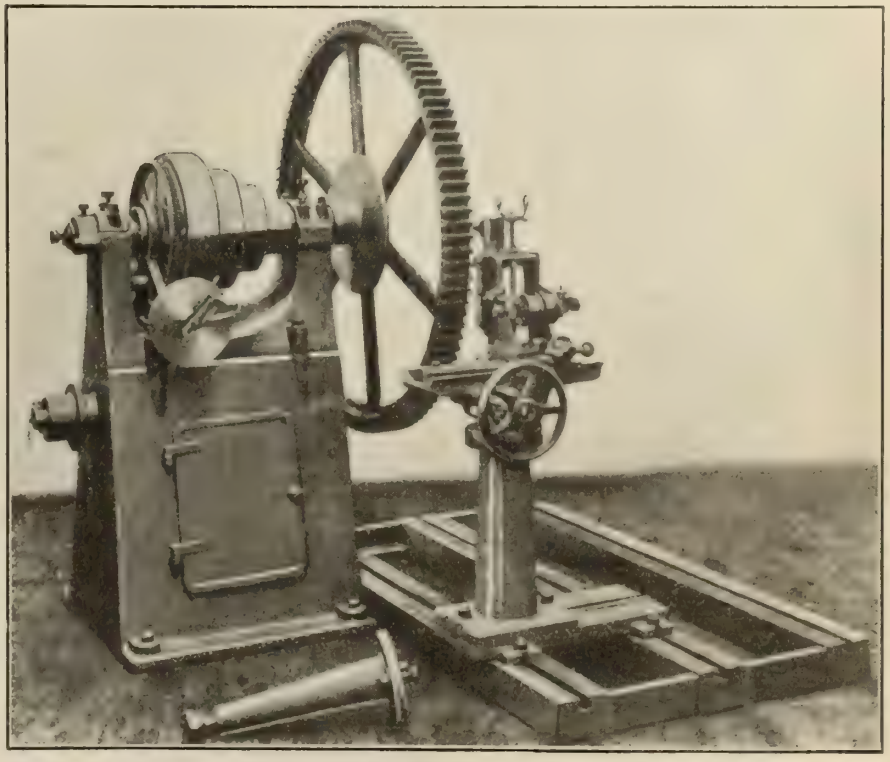


Ball Bearing Journal Jack.

Railway mechanics will be quick to appreciate the manifold advantages of being able to place a heavy timber on one carriage and do all the mortising, gaining and boring required, without having to carry the work about the shop. If gang boring can be done to advantage, the manufacturers' No. 163 multiple boring machine is added to the equipment.

The hollow chisel mortiser used in this combination is of the most powerful type built. It will mortise from ½ to 3 inches square and 6 inches deep. By reversing the timber, the mortise can be made 12 inches deep.

The No. 150 car gainer with a 16 inch head will cut a gain 5 inches deep in timbers up to 20 inches thick and 24 inches wide. The cut can be made on either the forward or return movement, or both ways as desired.



Combination No. 214 Vertical Hollow Chisel Mortiser and No. 150 Automatic Car Gainer Machine.—The Fay & Egan Co., Cincinnati, O hio.

MACHINE FOR CUTTING GEAR PATTERNS.

WE illustrate herewith a machine which has been designed by A. Ransome & Co., Stanley Works, Newark-on-Trent, England, and is built by them for cutting teeth on the patterns of spur or bevel-wheels of any diameter up to 6 ft., and of any pitch. The same machine can also be used for turning the wheel patterns before cutting the teeth. The mandril runs in long adjustable gun-metal bearings, and is fitted, as shown in the view, with a four-speed cone, which comes into play when the machine is used as a lathe. Double-thrust ball-bearings take up the end play of the spindle.

A dividing apparatus fixed to the head stock is provided for accurately cutting the teeth; it can be adjusted for teeth of all numbers up to 50, and in some

Machine for Cutting Gear Patterns. Makers, A. Ransome & Co., Newark, England.

cases up to 312. There is no difficulty in fitting the machine with dividing plates, for other numbers of teeth. The dividing apparatus, which is thrown out of gear when the machine is used as a lathe, consists of a worm-wheel 17 in. diameter, driven by a worm with dividing-plate for the required number of teeth. The plate is made with concentric circles, each circle having differently spaced holes, there being provided an

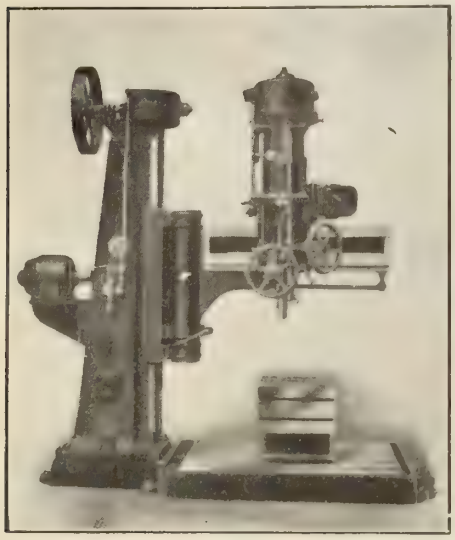


Fig. 1.—Hydro-Pneumatic Drill.

adjustable stop for accurately measuring the exact number of holes required for the various numbers of teeth.

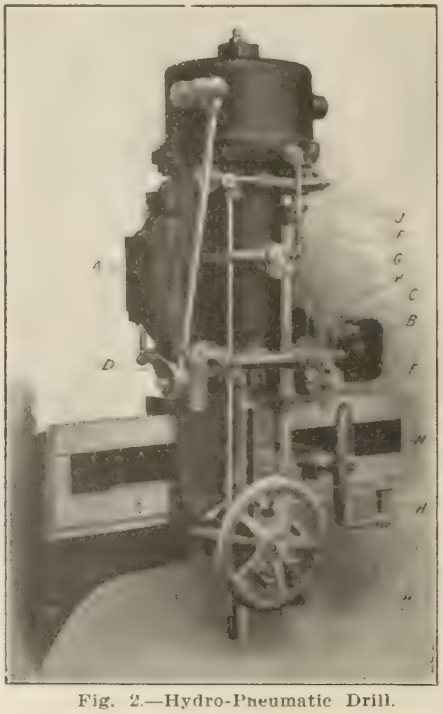
The teeth are cut by means of a spindle running in ball-bearings, fitted with a steel cutter-holder, and driven by a light belt from the overhead countershaft. The spindle is supported on a carriage having a vertical adjustment for setting the cutter exactly central with the wheel, and a fine screw adjustment for setting to the exact depth of tooth. The carriage is traversed by means of a rack and pinion operated by a hand-wheel. The apparatus is also made with a swivelling motion for cutting bevel or mitre-wheels; it can be easily adjusted on the bed to suit wheels of various dimensions.

HYDRO-PNEUMATIC DRILL.

THE Walter H. Foster Co., 50 Church St., New York, have lately put on the market an interesting type of radial drill, which is illustrated in Fig. 1. The most noticeable difference from standard types of radial drills lies in a combination of the saddle on the arm and a cylinder with gear box on top, containing high and low speed gears for variation of spindle speeds, in connection with a variable speed motor. The cylinder, through which the spindle passes, is surrounded by an oil chamber, and the piston which slides in it is connected with the spindle. The latter revolves in the piston, and takes its thrust on ball bearings. The spindle is driven by a D.C. variable speed motor, directly attached to the cylinder through a set of gears, which gives two speeds of spindle for each motor speed. The spindle may be made to rotate in either direction through a drum type controller, and when used for facing or tapping, may be operated by a hand wheel.

The vertical movement of the piston, or in other words the feed of the drill, is obtained by the admission of air at about 80 pounds pressure to the top of the piston. Below the piston the cylinder is filled with oil, and on the admission of air to the top of the cylinder this oil is forced through a graduated valve into the chamber surrounding the cylinder. To raise the spindle again, air is admitted to this chamber, forcing the oil back and thus raising the piston and spindle. The arrangement gives a steady feed, and the absence of backlash reduces to a minimum, the danger of breakage should an extremely hard spot be met with, or when breaking through at the finish of a hole.

A constant speed motor is provided for raising and lowering the arm, or fast and loose pulleys are furnished if desired. A feature of the head is its adaptability to other makes of radial drills on which the drill head may be so much worn that considerable expense would be necessary to repair it. Should the base, column and arm of such a drill be in fairly good condition, the application of the hydro-pneumatic head would, it is thought, result in an up-to-date machine,



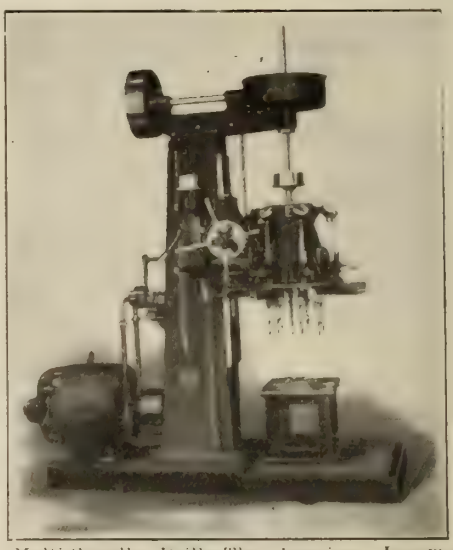


Fig. 2.—Hydro-Pneumatic Drill.

absorbing considerably less power than a geared machine, and capable of driving high speed drills to their full capacity.

The enlarged view of the head, Fig. 2, shows quite clearly the absence of moving parts. The motor is shown at A. The drum type controller B, is of new design, having ten points of contact, and has the resistance C, attached in a very

Multi-Spindle Drill The American Locomotive Co.

neat and compact form. The lever D, operates the high and low speed gears through a clutch.

The feed operating valve E, has a flat seat graduated to permit the passage of oil from the cylinder to the surrounding chamber and as the air pressure on top of the piston in the cylinder forces the oil, which is under the piston, through these graduated passages the feed is constant. The four way valve F, controls the passage of the air, whether it shall be on top of the piston forcing the spindle down, under which condition the oil is being forced into the chamber through valve E, or forcing the oil back into the cylinder under the piston, thus returning the spindle to its original position; the air valve is operated by the vertical shaft G, carrying adjustable trip dogs H.H., which are arranged to swing out of the way when the spindle is operated by hand, and not interfere with tappet I, which slides with the spindle.

The by-pass valves J and K, operated by lever L, through the connecting rod, allow the air and oil to pass freely in either direction while operating by hand. The hand wheel M, has pinion engaging with rack for hand operation of spindle. The hand wheel N, has spiral gear engaging rack for adjustment of head on arm.

ALL-GEARED MULTI-SPINDLE DRILL.

THE multi-spindle drill here shown was designed by the American Locomotive Co., for use in their automo-

bile factory at Providence, R.I. To drill the tough alloy steels used in the construction of the automobiles made necessary the bringing out of a multi-spindle drill which would give an equally high efficiency compared with other high-speed drilling machines.

The ordinary type of multi-spindle drill, in which the spindles are driven by universal joints, was found to be unequal to the strain, consequently in the present design, gears were employed for driving; universal joints being entirely eliminated.

The sales agents for this drill are the Walter H. Foster Co., 50 Church st., New York.

MULTIPLE DRILL FOR DRILLING MEAT CUTTER PLATES.

WE illustrate in Fig. 1 a large size multiple drilling machine of the raising table type. It was adapted for drilling meat cutter plates and equipped with six interchangeable heads, each with a different layout of spindles, and a table fixture for locating, holding and indexing the cutter plates during the process of drilling the holes.

Fig. 2 shows five of the interchangeable drilling heads, the sixth being shown in the machine with a drilling steady jig attached. Each head is furnished with a four leg cradle for safe keeping when not in use, and also to facilitate handling and adjusting it to and removing from the machine.

Fig. 3 shows the six cutter plates drilled with these heads. Above each plate is given the total number of holes; the number of spindles required to do the drilling and the number of operations. The distance between the holes in these plates is about 1 1-3 drill diameters.

Constructional Details.

The drilling heads are self-contained and are easily and quickly interchanged by means of the cradles before mentioned. The heads and spindle drivers are made of the best brand of bearing phosphor-bronze, and the drilling-spindle holes are bored to within .0005 inch limit as to location. The spindles are of tool steel, and cut out of the solid bar. They are hardened, tempered and ground true to size, and are fitted with pinch chucks for taking listed straight shank tongued wire twist drills. The steady jig mentioned is clamped to the lower end of the drill head and is adjustable vertically to allow the cutting end of the drills to project out just sufficiently to drill through the cutter plate. The steady jig shown is used on the four smaller heads, the only alteration required, being the exchange of steel plates containing the jig bushings that are held in place in the lower opening of the steady jig by screws.

Other heads with layouts of spindles arranged within a five inch circle can be used in this machine. The drill head casing is removable, and other casings may be fitted to take in larger heads, in which the spindle layouts are not larger than an 11-inch circle. The main driving spindle is 1 5-16-inch diameter, and runs in loose perforated bushings in both upper and lower bearings, thereby increasing the resistance to wear and heating-up, at high speeds. Lubrication to all high speed parts connected to this spindle, is affected through a capped brass oiler screwed into the upper end of the main spindle, the oil leading down through a hole drilled the entire length of the main spindle to the drilling head. The oil, in gravitating, and by its centrifugal tendency lubricates the upper and lower bearings. A separate oil well is provided for the upper bearing.

The Raising Table.

The raising table has a working surface of 12½ x 20 inches, and has an oil run on all sides, with an outlet on each end leading to the oil pan beneath. The table has a feed of 9 inches and is actuated by an 18 inch hand wheel through a pair of gears, pinion and rack. The leverage ratio of the table feed is 30 to 1. A stop screw is provided for drilling the required depth. The distance from the lowest position of the table to the end of the drills is 10 inches. The distance from the main spindle centre of the table to the inner side of the column is 6⅞ inches. The table supporting arm is adjustable and can be clamped at any height required. The supporting arm is raised and lowered by meant of the ratchet-pawl and rack-pinion method, and is located on the left-hand side of the machine.

On the table, Fig. 1, is shown the cut-

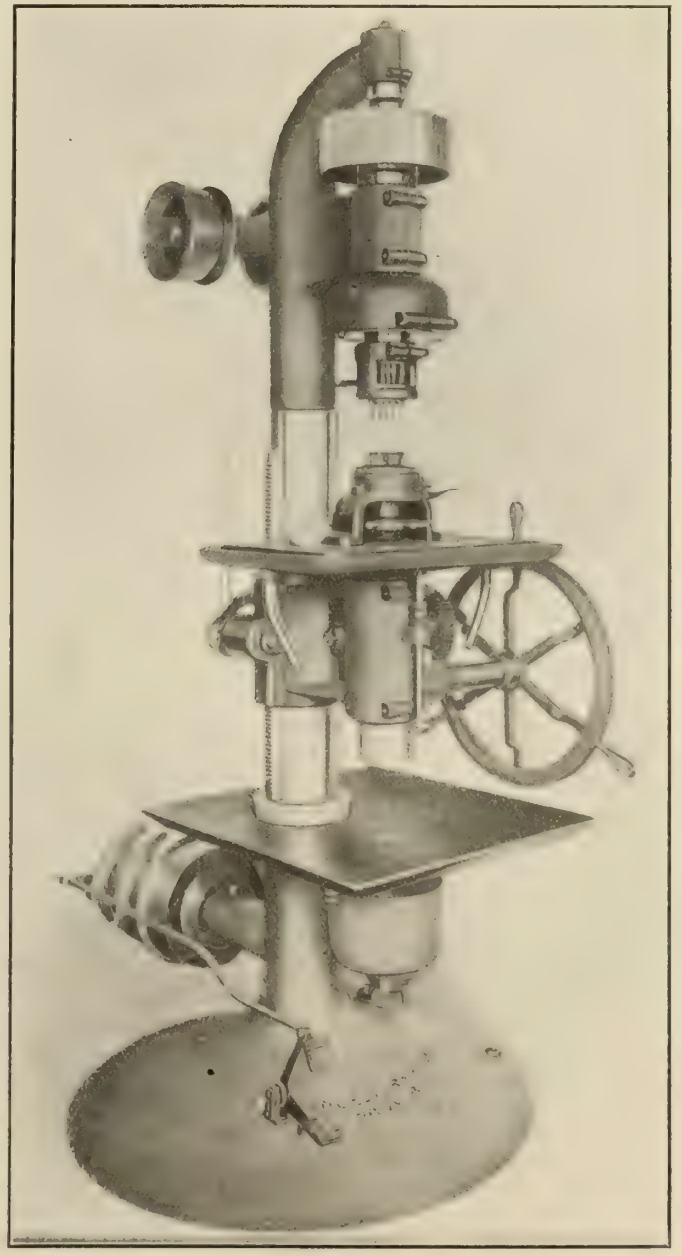

Fig. 1.—Multiple Drilling Machine, Raising Table Type.

ter plate fixture. It is centralized with drilling head and is fastened to the table by screws. The functions of this fixture are locating, holding and indexing the cutter plates for the operations in drilling. An expanding arbor projecting above the top face of the indexing head of fixture, both centralizes and holds the cutter plate by means of the hole in its centre. The cutter plate is seated on three short steel posts on indexing head. The arbor is expanded by means of spoked hand-wheel seen in front opening of fixture. An indexing head and expanding arbor are required for each plate and are easily and quickly interchanged. The indexing head of fixture is moved by hand and locked by a pin actuated by a downward pressure on small lever at the right.

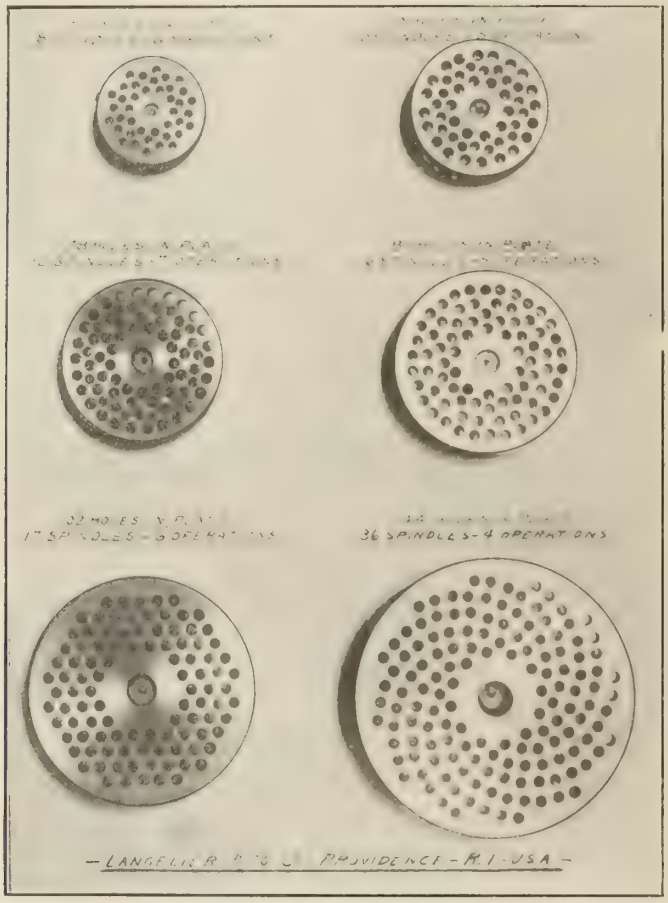

Fig. 3.—Drilled Cutter Plates.

Cutting oil is supplied to the drills by an oil pump. The oil after usage, gravitates into the lower oil pan and is filtered twice before entering the supply oil tank to be ready for use again. On the base of the machine is located the tight and loose pulleys, the pump and driving pulley for the quarter-turn belt. All of these are fitted with loose perforated bushings. The machine is started and stopped by a foot belt shifter. The main spindle and drill head spindles run at 800 r.p.m.; the floor space is 33 inches; by 42 inches; the height, 6 feet 8 inches; and the net weight about 1,750 pounds. The Langelier Mfg. Co., Providence, R.I., are the makers of these machines.

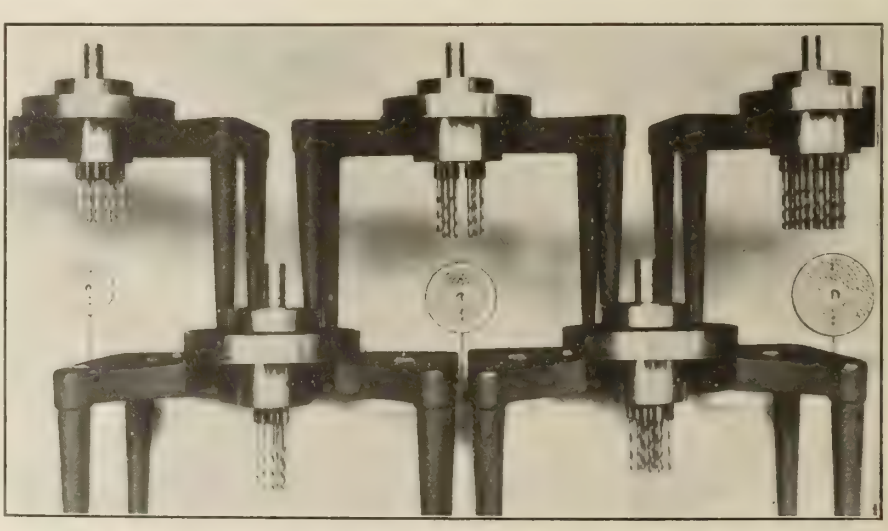

Fig. 2.—Interchangeable Drilling Heads, Multiple Drilling Machine.

A FIRST IMPRESSION.

There is a saying that first impressions are lasting. These first impressions that many a visitor gets in a shop come to him from the reception or waiting room. If he is discerning, what does he think of the uptodateness of the concern when he finds before him a table covered with a motley, disordered collection of magazines and periodicals with the uppermost ones months old? If his call is in August, he may pick up at first a paper of December of the year before, or a journal of the preceding February, or a magazine of March. A very little of the ambitious office boy's time would keep the files of regularly received periodicals up to date, with the current number on top. This is a small matter, but one, that properly attended to, promotes an air of general efficiency. —Ex.

BOTTLED SUNSHINE.

When a man in the States makes up his mind to "get on or get out," his efforts to get-rich-quick are a perfect godsend to the financial specialists in this line. Two such specialists have recently obtained $1,000,000 from persons in a hurry to speculate on "bottled sunshine." The imposture shows commercial enterprise worthy of a better cause. The organizers duly worked up their publicity department, "plants were erected in New York, Philadelphia, Baltimore and other cities." Each "plant" comprised a series of mirrors to catch the sunshine, wires carried the energy from the mirrors to certain storage jars; to these jars incandescent lamps were connected. When the sun shone the lamps lighted up beautifully; it was marvellous how those little mirrors could keep a great bank of lamps going. Even quantitative data were supplied to the spectators. one sunny day would light any office building for a week. Some fool of an electrician must have thrust himself in, however, and before the patentees could get aboard the lugger with their swag, the Federal authorities laid hands upon them.—Meteor. E. T.

EDUCATION AND ABILITY.

IN another part of this issue of Canadian Machinery will be found a short illustrated descriptive article covering the Montreal Technical School. This recently opened and expensively equipped institution owes its being, as do others under project in leading cities of the Dominion, to a laudable desire to provide adequate facilities for the acquirement of a technical education by those engaged or about to engage in industrial enterprises as operatives.

Experience goes to show that many men of education, technical and otherwise, are and have been in the positions occupied, much in the nature of the "square pin trying to fit into a round hole." In other words they lack ability, that subtle inborn talent which suits a particular sphere and utilizes much or little education to adorn it. We are disposed to think that the broadcast dissemination of technical training will tend to an increase of such undesirable contingencies, unless steps are taken to determine a student's native ability and aptness for a particular profession, previous to the unloading of theory or technicalities on him by means however skillful.

It is a general experience that most things are improved by cultivation, therefore, the imparting judiciously of technical education will improve the operative in our workshops and factories. Men are endowed with a diversity of gifts, some have a number, some apparently, have one only, or, generally speaking, a very few. Some have brilliant gifts, while others are more commonplace. There are men who will make good and forge ahead, irrespective of technical schools, and there are those again, who need the training which the latter imparts. The true success of any technical school will not depend, however, on its equipment and facilities for imparting knowledge, but on its early sifting-out of each student's inherent bias, and training of him accordingly, so that he fills his proper niche to his own profit and to those with whom he may be associated.

Education, technical and otherwise, fits a man earlier to fill more perfectly his place as a workman and a citizen, but may not transform a man with musical gifts into a successful boilermaker. Much attention is devoted to a student's physique when considering his fitness for adopting a trade or profession, but little or no heed is given to the capacity of his brain and hereditary inclination.

CO-OPERATION.

IT is generally conceded that every enterprise which depends for its success on the aggregate efforts of a lesser or greater number of individuals, must have a more or less perfect co-operation of its units towards the desired end. While this is true, we are afraid that only a very limited realization, compared with what might be, is the daily universal experience. No sphere, in which we as individuals play a part, is exempt, for each, the political, the civil, the religious, the social, the domestic and the business world, shows that absence of co-operation and persistent personal presence, which make for strife and hinder progress.

In the business and manufacturing field, what do we actually find? Co-operation between employer and employees, between departments and individuals composing these departments, to the extent only, that some machine or other may be produced and sold to earn for all a previously determined or estimated return in gold. To attain this, organization, system and discipline of the highest proved efficiency are brought into operation. The spirit actuating the employer is neither humanitarian nor philanthropic, and we regret to say, that to an equal extent is the same true of the employees. Labor troubles would be of less frequent occurrence were the humanitarian aspect given more consideration by the former, and if a fairly large percentage of the latter realized of how little importance their "assumed officiousness" was to anyone outside of their own "charming" personality.

The exigencies of life determine in their unregenerate essence that the weak, unprotected and inequipped shall go under; yet no man or body of men dare practice or take advantage of this with impunity, by get-rich-quick schemes or other unworthy means. Co-operation on the part of the employer with his employees must to-day be real and unselfish, for the latter in ever-increasing numbers of labor's best element, are men, shrewd, educated and sensitive to injustice. Co-operation between manufacturing departments rests also largely with employers, for so long as output cost systems make it possible for one department to produce cheaply at the expense of another, to a corresponding extent, in this feature also, will there be always a spark of strife and a want of highest realization.

Co-operation among individuals comprising any department is in a majority of cases far from being as fully consummated as it ought. The desire to gain favor from superiors, and the unwise recognition of efforts in this direction by those to whom it appeals, and they are many and everywhere, is, we believe, the cause of more inefficiency and loss of monetary return, than is possible by either tyrannical proprietorship or departmental jealousy or both combined. The trouble is widespread, and none of us need look past our own nose for its evidences. So long as those in charge present an open ear for the reception of gossip from "suckers" instead of presenting them with a "good swift kick," just so long will there be lack of co-operation between employees, and diminished profits for the employer.

The Evolution of Armor Plate in the British Navy

By Frank Walker

IN 1860, the French Government launched and commissioned the line of battleship "La Gloire," possessing all the characteristics of the wooden vessels of that period, with the addition, that the free-board of her broadsides was protected for more than half its length by closely jointed wrought iron plates 10 centimetres thick. The "entente" at that time was anything but "cordiale," and Britain at once replied by building at the Blackwall yard of The Thames Iron & Shipbuilding Co., "The Warrior," our first "iron clad." The sides of this vessel were protected for about two-thirds length, by wrought iron plates 4½ inches thick, the plates being rolled at the Parkgate Iron Works, Rotherham, near Sheffield. "The Warrior" was launched in 1861, and work was thereafter commenced on an improved type vessel, "The Minotaur."

Armor Plate Development.

In 1862, the late Sir John, then plain Mr. Brown, perceiving that armour-plate had come to stay—with characteristic shrewdness, laid down at The Atlas Works, Sheffield, a complete plant for the manufacture of iron armor. This example was followed in the next year—1863—by Mr. Charles Cammell, of the Cyclops Works, and for a number of years after these two firms had the distinction of possessing the only armor-plate plants on British soil. That they reaped a golden harvest goes without saying. Their wages bill to workmen was of immense proportions. The plates were composed entirely of best puddled iron, and the demand for skilled workers far exceeded the supply, with the result that most extravagant salaries were paid to all employees. Those were indeed red-letter days for the iron worker; even such lesser lights as coal and ash-wheelers were paid wages which made the skilled mechanic squirm with envy. Puddlers, shinglers, ball-furnace-men and "muck" rollers, were simply coining money, while the "head-serangs," the armor plate rollers and furnace men, were in receipt of incomes which would not have disgraced high dignitaries of the church, etc.

Improvement in Guns and Projectiles.

The advent of armor naturally resulted in great improvements being made in naval guns and projectiles, and in order to afford protection against these, the plates grew thicker with each succeeding ship or class of ships, until in 1876, the climax was reached in "The Inflexible," the sides of which were protected by iron armor 24-inches thick.

About this time, Mr. — afterwards Sir Alex.—Wilson, of Cammell & Co., perfected and patented his compound armor plate. This plate, as adopted by the British Admiralty, consisted of a Bessemer steel face rolled on to a puddled iron backing, and its superior resisting power enabled naval constructors to cut down the thickness of armor by more than one half. This was not for long, however. Krupp, at Essen and Armstrong, at Elswick, kept things moving, and in order to resist their improved guns and shell, the thickness of the compound plate crept upwards by half inches and inches till it reached in "The Benbow," launched at Blackwall, in 1884, the thickness of 21 inches. Mr. Charles Ellis, of Brown & Co., stepped into the breach with an improvement in compounding, which caused things to remain stationary for a while, but the guns still continued to get the better of the argument. Then Harvey, the American, came forward and with his splendidly simple solid steel cemented plate.

The Harvey Armor Plate Process.

Taking advantage of the well-known characteristics that iron possesses of absorbing elements with which it is kept in contact for a length of time at a certain temperature, Harvey packs a low carbon open-hearth steel plate in charcoal and pure white sand; the charcoal being on the face of the plate and the sand on the back. Baking in a special furnace, at a temperature of 1,300 degrees F. for a period of from 12 to 14 days follows thereafter. By the cementation process, the face of the plate absorbs carbon from the charcoal, while in a like manner the back absorbs silicon from the sand. After special heat treatment and quenching, the super-saturated carbon face of the plate becomes intensely hard, while the siliconised back remains extremely ductile, and makes an ideal armour plate, at once compound and homogeneous. These plates had a superiority of 75 per cent. over the compound types, and were at once adopted by the Admiralty; the thickness of the belt and casements being reduced to 6 inches. This state of affairs did not last long, for the introduction of the long calibre, wire wound gun, the capped and chilled projectile, and higher powered explosives, called for further resistance, and we find on "The Canopus," built in 897, battery armor 72 inches thick.

The Krupp Cemented Plate.

The next important move in armor brings us to the present day, and to the Krupp cemented plate. This plate was the outcome of a better knowledge of the chemistry of steel and of the effect of mixing with it small quantities of various rarer metals. Steels made in this way are known as alloy steels and possess extremely high resisting powers. The original Krupp plate was made from open hearth steel containing 3.5 per cent. of nickel, 1.5 per cent. of chromium, and .25 per cent. carbon. Latterly, .15 per cent. of vanadium has been added. This plate is treated, as in the Harvey process, by cementation, and after a very refined series of heat treatments and quenchings in oil and water, becomes almost mechanically perfect for the purpose in view. A 12-inch plate manufactured under this patent in 1890, by Cammell & Co., successfully resisted three point blank shots from the 9.2 inch calibre naval gun.

The Introduction of Vanadium.

The enormously increased power of the modern gun has not allowed the armor to be greatly reduced in thickness of late years, but it is interesting to note that the introduction of vanadium was accompanied by a reduction of one inch in the thickness of the side armor of the "Super-Dreadnoughts." "The King Edward VII," "Dominion" and "Hindustan" had 9 inches, "The Lord Nelson" and "Agamemnon" 10 inches, "Dreadnought," "Bellephoron" and "Temeraire," 11 inches. While "The St. Vincent" and "Collingwood" with vanadium alloy, had 10 inches. These thicknesses apply to belt armor only and not to gun-shields or conning towers. In all probability, a return may be made in the near future to the compound plate, as an Englishman named Simpson has perfected a means of welding tungsten-alloy-steels, and a plate composed of 2 inches of tungsten steel rolled on to 4 inches of chrome-vanadium steel has been tested and found to be 50 per cent. superior to a Krupp cemented plate of equal thickness.

In conclusion, I would point out that the study of high-class alloy and carbon steels is one of absorbing interest, and I would commend it to all students of chemistry. Although we may not all become Wilsons or Harveys, yet we must remember that the steel industry is one to which the old adage does not apply, for the more cooks we have the better the chance for getting good broth.

The Brooks plant of the American Locomotive Company has been closed for an indefinite period, and 4,200 men are laid off.

FOUNDRY PRACTICE AND EQUIPMENT

Practical Articles for Canadian Foundrymen and Pattern Makers, and News of Foundrymen's and Allied Associations. Contributions Invited.

MAKING A BULLDOZER CASTING.

By Jabez Nall, Cleveland, Ohio.

IN the pattern-making and molding required for the production of the casting shown in general view, Fig. 1, and in side elevation and sectional drawings, Figs. 2, 3 and 4, respectively, there are several special features that may be of interest to readers of Canadian Machinery.

The Pattern Question.

Those affecting the patternmaker, and which he must take into consideration before commencing the actual work of making his pattern, are as follows: First there comes the method of molding. We hear much about consulting with the molder in such matters, but this is not always possible or satisfactory, when carried out, and as a rule it is up to the patternmaker to decide finally. For best results to this end, however, it is necessary that the patternmaker be familiar with up-to-date foundry methods, and have a practical knowledge of molding in all its branches. I have always tried to impress and interest the patternmaker in the foundry end of his business, but with indifferent results. Without this knowledge he is incapable of considering or comparing the cost of different ways of molding, and may construct his pattern in such a way that it adds unduly to the foundry cost of producing the casting. This, too, may be done with no saving in the cost of the pattern. It should be borne in mind that the pattern and the mold are but means to a desired end, i.e., a perfect casting, accurate in dimensions, of clean, solid metal, and as free from shrinkage strain as possible. The appearance of a casting is also an essential of quality.

In all large castings, and in many smaller ones, there is usually more than one way to do the job. For instance, this pattern could be made to mold on the side, and from the point of view of the patternmaker and of the molder, would present some advantage over the plan adopted. Smaller sizes, up to about 7 feet long, of other proportionate dimensions, and of similar design, I have made thus, with a good core print bearing on either side. The results were entirely satisfactory, due to the smaller amount of metal. Such a method does away with all loose parts of pattern—a very desirable feature, when it can be attained without sacrificing anything more essential. With a heavier casting it becomes a matter of doubt whether we would get solid, clean metal on the cope side, with an even contraction. The prime consideration in making the larger sizes by the method described in this article was to get the heavy part of the metal at the bottom of the mold, so gated that it had a chance to rise equally on both sides, thereby assuring as far as possible an even contraction. The result, as seen in Fig. 1, showns a perfect casting on all machined surfaces.

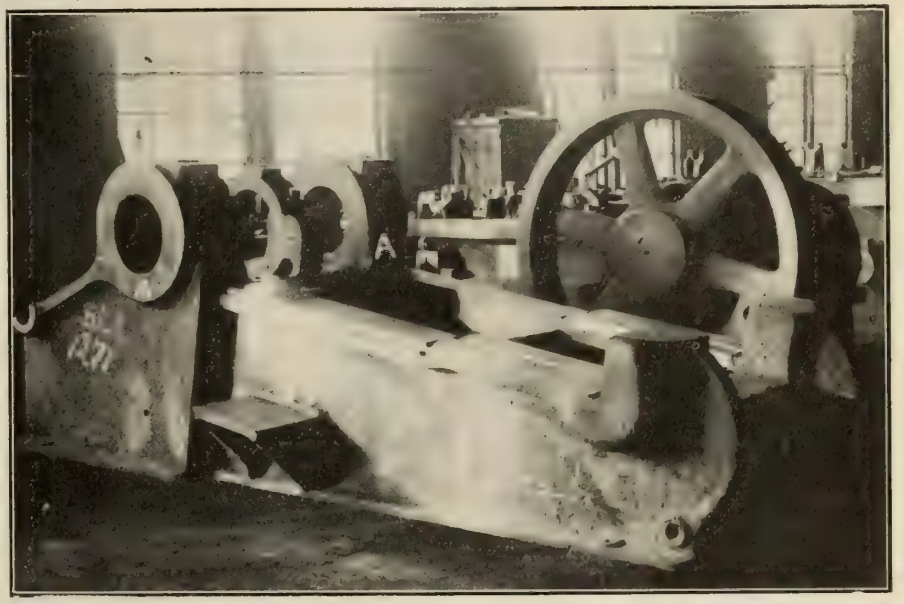

Fig. 1.

The casting being of steel, it was a question whether we would succeed in

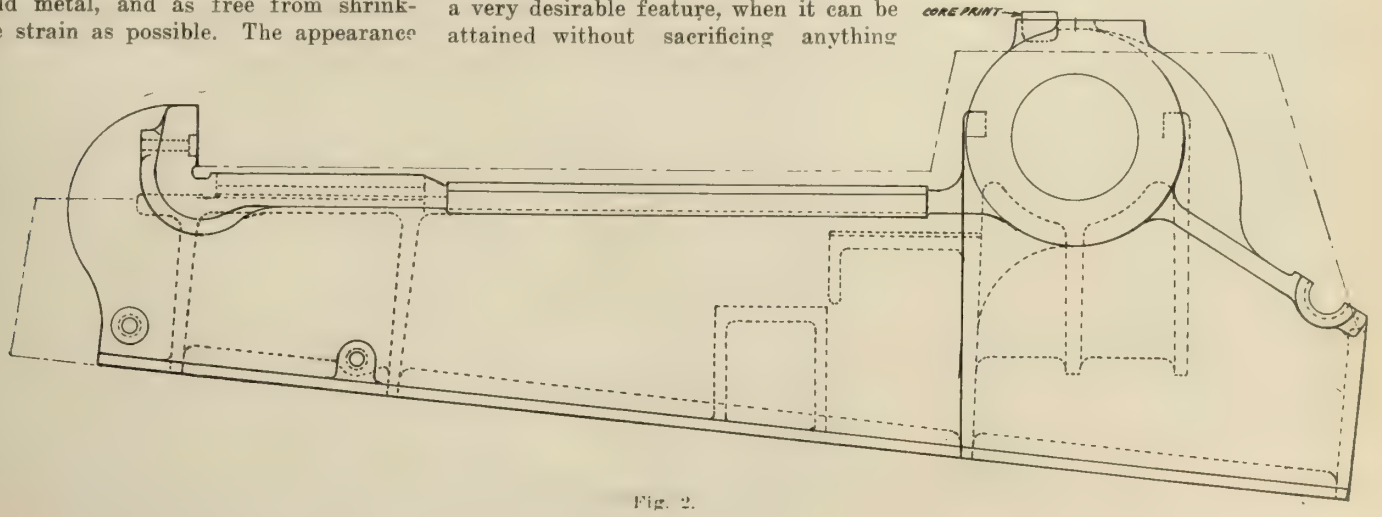

Fig. 2.

getting solid metal around the crank shaft bosses, as marked at A, Fig. 1. To ensure this, it was necessary to provide a feeding head for these bosses. This was done by adding metal, 6 ins. wide, through the lightening cores of the side girders, Fig. 7, and connecting with the heads on top of mold. Without this addition, the metal was not of sufficient thickness to prevent freezing of the top metal before the heavier metal below solidified.

Metal Considerations.

The question of the method of molding being decided, next comes the consideration of the metal from which the casting is to be made, and the consequent amount of shrinkage allowance to be made. In this connection, the design of the casting and distribution of metal must be taken into consideration, as well as the method of molding, because a fully-cored mold has a tendency to retard shrinkage. Usually a pattern-maker is apt to make too great allowance for shrinkage, rather than too little.

On these castings at first I made an allowance of ⅛-in. to the foot, but experience taught that this was full, therefore, I afterwards used 1-10-in. to the foot, which proved as nearly correct as practicable.

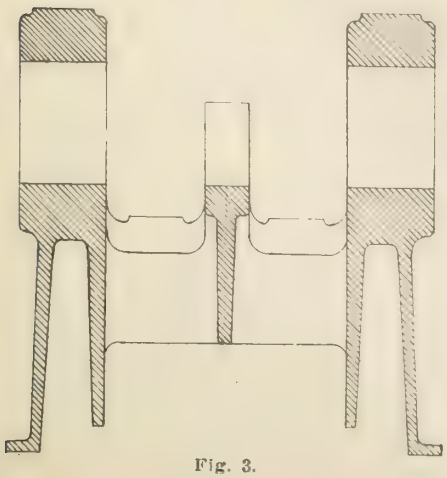

Fig. 3.

Working Layout.

These primary questions settled, the next requisite is a working layout of the job. For this purpose a full-size drawing of sections, as per Figs. 3 and 4, was made, having lines of core prints added, the importance of which will be recognized by the practical pattern-maker. We have seen much time lost on some jobs, in an effort to save making this drawing. Properly used, it is a time-saver and a preventer of errors, especially so where a number of men are working on the same job. On the other hand, we have seen time wasted by making a too elaborate working drawing, that had to be duplicated off-hand upon the work itself.

In this case, for the side elevation, the side boards were first got out from scale, then glued together and dressed off. The side elevation, as shown in Fig. 2, was drawn out on these, the position of the inside frames being laid off at the same time. As the pattern was of tapering height, this was essential to the correct making of the inside frames, of which, including the ends, there are seven. These frames being built upon the sectional layout, working from one centre line, the length of the upright was determined according to the position of each respective frame upon the side elevation. The framework was made of 1⅜x5½-in. stock, doubled in thickness, as indicated in Fig. 7, to the left, which shows the pattern in process of molding. With the frames made, the side boards were cut along the line of the offset at X, Fig. 5.

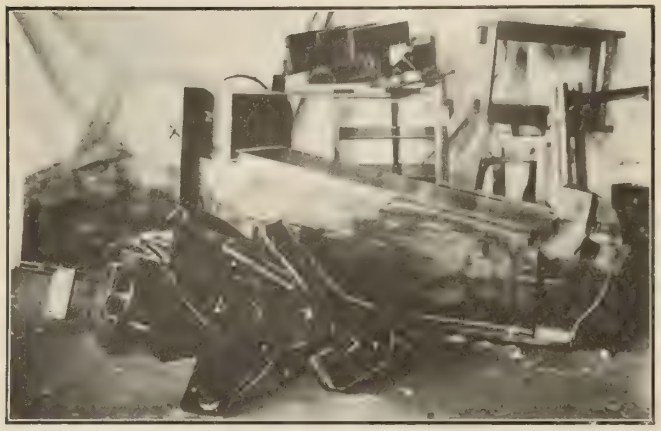

Fig. 5.

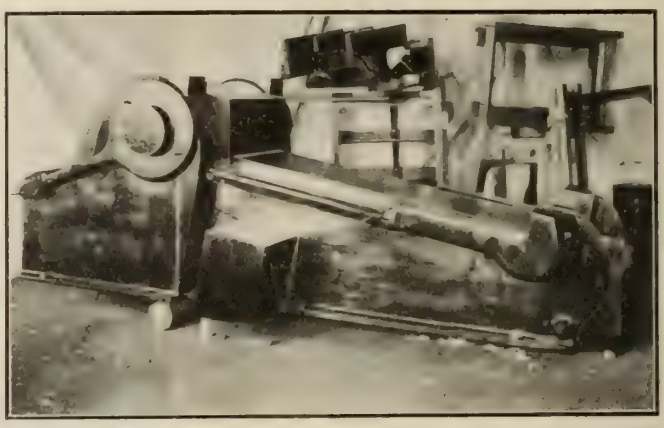

Fig. 6.

Figs. 5 and 6 give a view of the finished pattern, the former showing the loose parts removed.

The Mold.

The pattern being molded by the method known as "bedding-in-the-

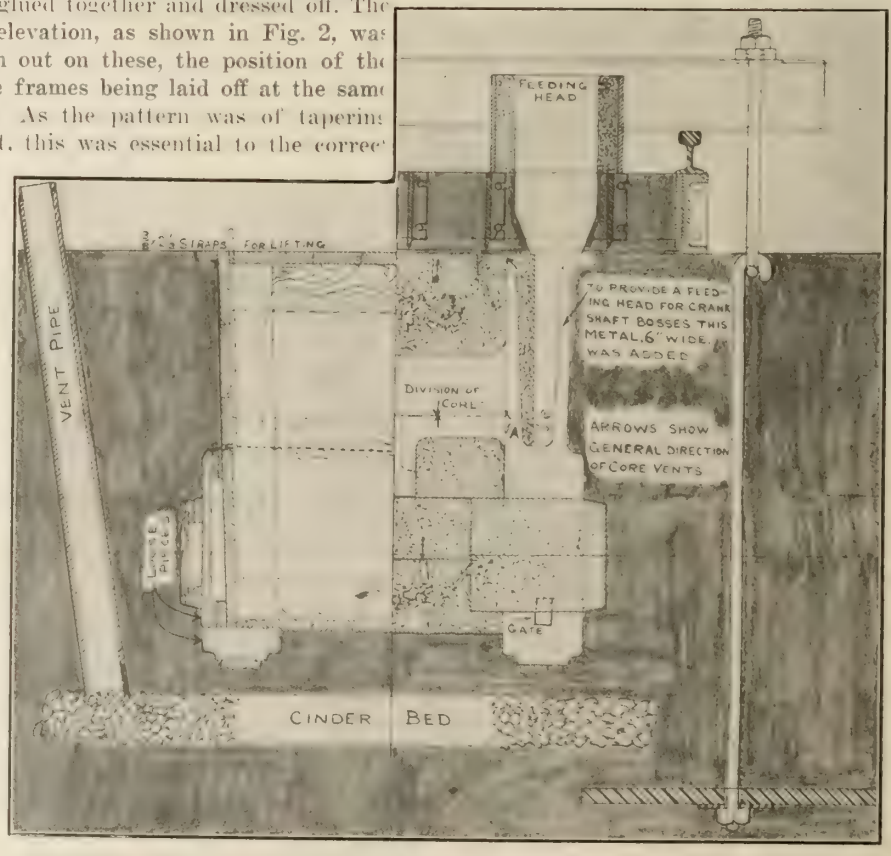

Fig. 7.

floor,'' the under side (when molding, it was, of course, inverted from the position shown in Figs. 5 and 6) was made as plain as possible, to facilitate the making of the bed. Several of the core boxes may be seen in the background, and are sufficient to indicate the division of the cores. Fig. 7 shows, to the left, a section of the mold, with the cope removed, ready to draw the pattern, and to the right, the completed mold. Details, such as rods, gaggers, bolt heads, etc., are purposely omitted to avoid confusion of lines. It is not our purpose to enter into a detailed description of the process of molding at this time, except only to note the method of locating the side cores, as shown at A, Fig. 7. Two or more chaplets were rammed up in each of these side cores, at a given line marked on the box, and left projecting the amount of the required metal thickness. Tested by template or gauge, a core print was placed at each side of the centre cores to form a place for the side cores to rest upon the chaplets aforementioned. This bearing against the centre cores assured the correct thickness of metal here. Afterwards, they were further secured by chaplets wedged on the opposite side to prevent movement under the flow of the metal.

In a steel casting of this length, with varying metal thickness and crop ribs, there is always the danger of shrinkage, strain and cracking or parting company at the corners. That this can be overcome by a judicious use of stitching or bracketing the corners, the use of chills and the casting-in of rods, is proved by the casting, as seen in Fig. 1.

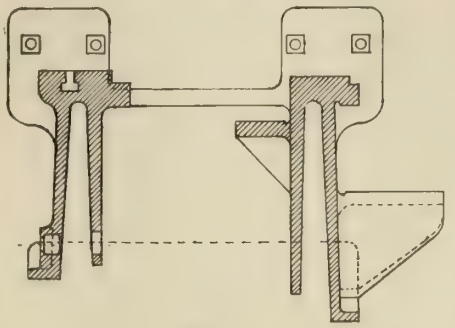

Fig. 4.

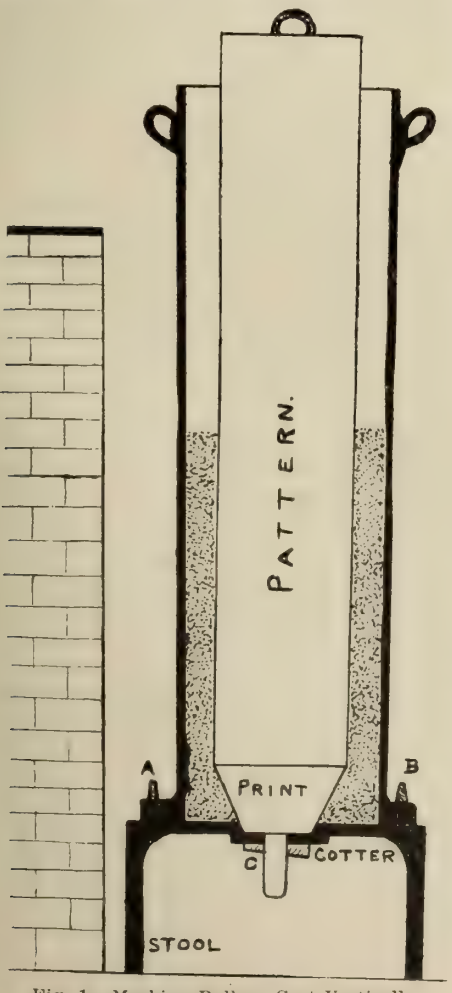

Fig. 1.—Machine Rollers Cast Vertically.

MACHINE ROLLERS CAST VERTICALLY.

By John H. Eastham, Montreal.

DURING the recent slump in the Lancashire cotton trade, local makers of machinery had great difficulty in obtaining sufficient orders to keep their works running three-quarter time. One firm of long standing suffered so severely through keen competition and the copy of their patent without actual infringement, that a reduction in the cost of production became absolutely necessary

Vertical Method Detail.

To this end, amongst other items, a roller job came under notice. With each machine sold, one 9 inch and one 7 inch diameter roller were required, of varying lengths, according to size of machine ordered. These had for years been moulded horizontally in ordinary pipe flasks, blackwashed and dried in the usual way, and cast vertically in a special pit for the purpose. The foreman decided to mould the rollers vertically in the above mentioned pit, for the reason that the clumsy pipe boxes required the crane too often.

In place of the old half block patterns on which both cope and drag parts were formerly rammed, solid wooden patterns were turned and provided with a staple for withdrawal from the sand. At the lower end a taper print was provided to guarantee the cores being placed in correct position as shown in Fig. 1. Casings cast in halves, and perforated at intervals with $\frac{3}{4}$ inch holes for vents, were made, in two widths and bolted together, to accommodate each separate size roller. About 3 inches ramming room was allowed all round the pattern. Cast iron stools, to serve as bases for casings and patterns, of sufficient height from pit floor to facilitate fastening patterns in place while ramming, and cores whilst pouring, were also provided, as shown in sketches I and II respectively. Each mould after being finished, and having the stool attached by cotters in guide pins ''a'' and ''b'', was hoisted on a stove car to the vertical position. Less coke was now needed, and less room taken up, by this arrangement than formerly.

By the addition of a little coal dust to the facing sand, blacking was rendered unnecessary, and after drying, each mould was lowered, into the pit, the core adjusted to place, the cotter shown at ''c'', figs. 1 and 2, driven tight, and the job cast as early as convenient. When shaking out, the cotters (not shown), were first removed from guide pins ''a'' and ''b''. The casing and casting were then hoisted from the pit, and emptied on to the foundry floor.

By this method, 40 per cent. of moulding time was saved, and castings true to pattern obtained; the former ugly joint mark, which had broken several valuable tools in the machine shop, being non-existent. The method of gating is shown in sketch of completed mould at fig. 2.

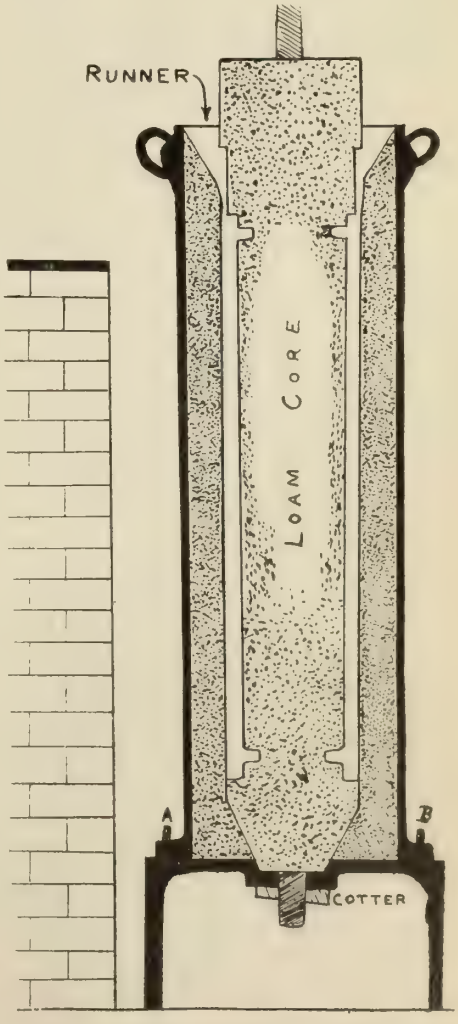

Fig. 2.—Machine Rollers Cast Vertically.

OPEN HEARTH FURNACES FOR SMALL CASTINGS.*

By Walter MacGregor.
Indiana Harbor, Ind.

IN discussing the subject of open hearth furnaces for the production of steel for small castings, I will confine my remarks to fuel oil furnaces, as operating with this fuel when the furnace is properly designed, the melter will have fewer difficulties to contend with.

Turning for a moment to the steam engineering profession, we see that the engineers in well conducted power plants are giving their greatest attention to the problems of combustion, and in the case of plants already in operation, experimenting to find a grade of fuel best suited to their type of furnaces. It is a well understood fact among these engineers, that the design of a furnace, to get the best efficiency from the fuel, depends entirely upon the nature of the fuel to be burned. Obviously, as we are to deal in high temperatures, we have, therefore, to pick out a fuel of heat value, and design our furnace to suit its combustion. In order to get the highest heat, our furnace body should be of such proportions, that we can burn the necessary amount of fuel, in the smallest possible space, and in order to burn a large amount of combustible in a small space, a short flame is necessary.

Short Flame Factors.

The factors governing the short flame, according to the fuel experts of the United States Navy, are :

First—A pure carbon fuel.

Second—Initial heating of the air which furnishes the oxygen for combustion.

Third—Intimate mixture of the oxygen with the fuel, or diffusion.

Fourth—Large surface of the fuel presented for impact of this oxygen.

The first factor, the nature of the fuel, is settled for us, because we have decided upon fuel oil, whose probable analysis is as follows :

C.—83.26 per cent.
H.—12.41 per cent.
S.— .50 per cent.
O.— 3.83 per cent.

With a specific gravity at 60 F. of .926.

The heat value of this fuel, according to Du Long's formulae, would be 19481 B.T.U. per pound. From this analysis we can easily compute the quantity of air required for combustion, and the products of combustion for any amount of fuel burned.

Open Hearth Furnace Requirements.

As a representative size of small open hearth furnace, we will choose five-ton as an example, and discuss the conditions that will determine the proper furnace proportions. We are to melt and reduce five tons of metal, and the time of charging one heat, till the time of charging that following, we will assume as four hours. As the oil consumed varies much in different furnaces, we will assume an average fuel consumption, say forty-eight gallons of oil per ton of steel melted in this given time, or one gallon per minute. Assuming twelve pounds of air required for burning one pound of carbon, and thirty-four and seventy-eight hundredths pounds of air required for burning one pound of hydrogen, we have from the analysis of the fuel :

9.9912 lbs. of air required to burn the total Carbon in fuel.
4.2161 lbs. of air required to burn the total Hydrogen in fuel.

14.2073
.16 Correction of am't for Oxygen in fuel.

14.0473 lbs. air required for complete combustion of 1 lb. of liquid fuel.

With fuel oil of 7.72 lbs. per gallon we have 14.047x7.72=108.37 lbs. air required per gallon of oil.

With air at 13.14 cu. ft. per lb. we have 108.37x13.14=1424.11 cu. ft. air required to burn one gallon of fuel oil.

Hence, to burn one gallon, we must admit theoretically 1,424 cubic feet of air per minute into the furnace. To this we must add the amount of air required in reducing the carbon and silicon in the metal. Ten thousand pounds charge, of which 12½ per cent. is pig iron with about 2½ per cent. carbon, and the rest steel scrap and billets of about .30 per cent. carbon, require reducing to about .18 carbon at the time of tapping. From this we get the total carbon contents of the bath as 56.5 pounds, to be reduced to 18 pounds, or 56.6—18=38.5 pounds of carbon to be burned out in about two hours of reducing the charge. As before, 157.6 cubic feet of air are required to burn 1 pound of carbon, therefore we have $157.6 \times 38.5 = 6{,}070$ cubic feet of air required in two hours, or 50 cubic feet per minute. All of this passes off with the products of combustion. In the same way we can determine the amount of air required in eliminating the silicon, and which will run about 42 cubic feet per minute. A certain amount of oxygen is also taken up by the manganese, but this is so small as to be neglected.

With the total theoretical amount of air required, $1{,}424 + 50 + 42 = 1{,}512$ cubic feet per minute, we are in a position to determine the proper furnace proportions, with due regard to the second circumstance in producing the short flame : "initial heating of the air." The volume of air is figured at a temperature of 72 degrees F., which will be about the temperature of air entering our valve. The increase in volume of air at different points along its travel, due to its increase in temperature, must be the governing factor in designing the ports, flue openings, etc., and as the volume of this air increases in direct ratio to the absolute temperature, it follows that the volume occupied at any point may be computed, when the temperature at that point is known.

The air valve, due to the reversing feature of the furnace, should be figured rather to accommodate the products of combustion than the entering air, as these are at a higher temperature, and will, therefore, require a greater area of flue. The temperature of the valve is a vital point in the problem of design, for any heat beyond this point toward the stack is lost as far as the furnace is directly concerned, and can only be used in the field of economizers. In determining the size of the valve we will first have to determine the velocity of the products of combustion through the valve, due to the draft of the stack. This then gives as our starting point, the design of the stack and which we would more naturally consider our finishing point.

Stack Design.

A number of eminent authorities on chimney design have chosen 600 degrees F., as the most economical stack temperature, and Rankine has spent considerable time in trying to prove it in his work on "Steam Engines." I have never seen an open hearth stack with that low temperature, and will, therefore, base my calculation on a temperature of 1,000 degrees F., because more nearly current practice. In my experience with small furnaces, I find that the most satisfactory stack draft to be maintained, is about one inch of water. This is a function of the height of the stack, and its difference in temperature inside and outside. With this difference in temperature and a draft of one inch of water, we get a stack 110 feet high, hence we will assume this as the minimum height to be desired. The velocity of gas, due to the pressure head for this height of stack and temperature, and allowing a 25 per cent. friction factor, is rather less than fifteen feet per second, a velocity recommended by a number of authorities as good practice.

We have based our calculation, so far, on the theoretical amount of air required for combustion, but will design our stack and flues, as in the case of power plant design, for an excess capacity of one hundred per cent., which would be 3,000 cubic feet of gas per minute, or fifty cubic feet per second. This, divided by the velocity of fifteen feet per second, would give a sectional area of stack of 3 1-3 feet, or a trifle over 2 feet diameter. We will assume 27 inches diameter of stack as best suited to this furnace, and plenty large enough to permit of any crowding. The size of the valve and flues leading to the valve

*Paper read at the American Foundrymen's Convention, Pittsburg, May, 1911.

from the checker chambers will be the same.

Checker Chambers Design.

The second factor governing the short flames, "the initial heating of the air," spoken of before, is introduced by means of the reversing feature of the furnace, through the checker chambers, and these chambers should be so designed as to slow up the travel of the products of combustion, in order that they may give up the major part of their heat to the checker brick, or that part of the heat which is not required to produce the stack draft. The cubical contents of these chambers should not be less than 75 cubic feet per ton of steel melted per heat, and preferably in the neighborhood of 100 cubic feet per ton. These chambers should be located behind the furnace and not immediately under the furnace. This point is quite as important in small furnaces as in large ones, as they operate at a higher temperature, and we should get the benefit of a good circulation of outside air, under the hearth of the furnace. These chambers should be long and narrow, or deep, in oil burning furnaces, giving a very long travel to the products of combustion, before they reach the valve, as on account of the highly volatile nature of the fuel and the slowness with which many of the hydrocarbons mix with oxygen, a great deal of the fuel will be out in the stack before it has undergone complete combustion.

Gas Analysis.

The methods of gas analysis, as applied to steam boiler practice, will show some very interesting relations in this regard. In a five-ton furnace which I have been operating, a flue gas analysis will show the following :

	CO	CO	O
At the rear of the checker chambers 24 ft. back of the centre line of furnace	6.4%	3.1%	.2%
In the air valve 9 ft. further back	8.8%	.3%	8.0%
In the stack 16 ft. further back	9.4%	.3%	9. %

With a decrease in temperature between the first and last point from 1,750 degrees F. in the rear of the chambers to 930 degrees F. in the stack.

In case all the fuel were burned before it reached the stack, the sum of the oxygen components of the flue gas would be 21 per cent., as there is 21 per cent. by volume of oxygen in all the air admitted to the furnace, the volume of the carbon element being so small as to be considered zero. As a matter of fact, however, the sum of the oxygen components at the valve is only 17.1 per cent., and even out of the stack it is only 18.7 per cent., which shows that there is some form of hydrocarbon gas occupying the other 4 per cent. and which is getting past the valve unburned, and being wasted out in the stack. This, I think, shows very conclusively, the necessity of having long chambers and flues in oil burning furnaces, to insure complete combustion of the gaseous fuel before reaching the reversing valve.

The above figures are based on atomizing the fuel with compressed air instead of with steam, because with steam, the hydrocarbons are slower in taking up oxygen, and a gas analysis at the valve will show a higher percentage of hydrocarbon gas unburned at the valve, and a corresponding increase in stack temperature. A sample of gas at the base of the stack, when steam was used for atomizing purposes, showed the following analysis : CO_2, 7.5 per cent. ; CO, .4 per cent., and oxygen, 9.5 per cent.

Oxygen and Fuel Mixture.

The third condition governing the short flame, "intimate mixture of oxygen with the fuel or diffusion," bears directly on the size and arrangements of the air ports and the furnace body. The size of the ports depends upon the size of the reversing valve, or vice versa, and the relation between the two is in direct ratio to the absolute temperature at the two points, these being 1,490 degrees F. at the valve, and 2,800 degrees F. at the ports, or a ratio of 1 to 2. The ports, therefore, should have an area of twice the area of the reversing valve, which will give us a total port area at one end of the furnace of about seven feet. These ports should be carried the full width of the furnace, to prevent any short circuit of air through the furnace body, as the travel of gas through the furnace body should have the same velocity at all points to get the proper diffusion. These air ports should come well up above the hole in the monkey wall, through which the oil burner enters the furnace, so that the air must come down on top of the flame rather than underneath it. This is a very important factor in designing a hot working furnace.

The space to be allowed for hearth in small furnaces should not be under ten square feet per ton of charge, and then, too, the shape should approach more nearly a square than the oblong forms in general use, as this tends to give a better effect to the radiation of the walls and roof Then, by widening the furnace, we lessen the cutting action of the flame on the side walls and keep down repair bills.

As to the length of the furnace body, this should be governed by the length of the oil flame, for the hottest part of the flame should be about the center of the furnace. I have not been able to get a flame that was intense enough to melt down a charge of metal any less than about eight feet from the tip of the burner to the hottest part of the flame, and as the tip of the burner should stick clear through the monkey wall, which will extend at least 9 inches beyond the ports of the furnace, we will get as a minimum furnace length, twice the length of the flame as already mentioned, plus twice the width of the ports, plus twice the thickness of the end walls, and plus twice the 9-inch extension of the monkey wall beyond the ports, or a total of about 22 feet.

Oil Burners and Antomizing Agents.

The fourth circumstance governing the short flame, "large surface of fuel presented for impact of oxygen," is a matter of oil burners and atomizing agents, and has furnished inspiration to thousands of inventors—all to very little purpose. The matter of atomizing this fuel oil is one of overcoming the surface tension of the oil and breaking it up into very fine particles, so that it will present greater surface for contact with the oxygen. The two methods in use, superheated steam and compressed air, give a mechanical efficiency so small that you can barely find it at all.

There is a great deal of discussion at the present time on the needless waste of compressed air for atomizing purposes when superheated steam will answer, but in the small casting business, one of the main difficulties is getting the metal hot enough to run the thin sections in the molds, and since by its very nature, compressed air, while atomizing the oil, furnishes at the same time oxygen for combustion, and that too very intimately mixed with the oil, it is quite evident that by using air we get quicker combustion, a shorter flame and a somewhat hotter furnace.

In conclusion, I will say that in operating a furnace designed along these lines, it will not be a difficult matter to get out six five-ton heats in 24 hours, and still have the metal hot enough to pour many castings weighing a fraction of a pound each. With a five-ton heat it is not uncommon to pour as high as 17 molds, consuming about 50 minutes in pouring. The metal must, therefore, be extremely hot at the time of tapping the heat.

GYPSUM IN NOVA SCOTIA.

In no other territory in the world, it is asserted, are there such vast, varied, and valuable deposits of gypsum as in Nova Scotia. The exposures show beds of from a few feet to hundreds of feet in thickness, ranging in color from gray to snow white, and frequently of the best quality. Some of the deposits have been worked for nearly a century, but so far only two mills have been established for the manufacture of gypsum products. The production of gypsum rose from 300,000 tons in 1908 to 322,974 tons in 1910, practically all being sent abroad.

EXHAUST FAN RECORD.

The Canadian Buffalo Forge Co., Ltd., Montreal, has perfected a slow speed multi-blade exhaust fan which has proven exceptionally economical in power consumption.

The high efficiency is attributed to the multi-blade design of the fan wheel, and to its proportions, which give maximum efficiency at speeds averaging fully 30 per cent. below the normal for exhaust fans. Slow speed is an important feature, as it reduces power consumption, minimizes wear and cost of upkeep, and lengthens the life of the fan.

The applications of these fans, are almost as numerous as those of standard design; sawdust, shavings, spent tan bark, refuse from abrasive operations, grain, wool, cotton, dust, smoke, gases etc., being easily and economically handled.

The fans are made single or double, in sizes from 30 up to 80 inches in diameter, and for pressures from one to six ounces. Like the "Buffalo" standard exhaust fans, they are made with reversible housing. Structurally, they embody all the features of the most advanced fan practice.

Personal

Mr. Bruce Harman, for many years a prominent member of the staff of the Linde British Refrigerator Company, London, England, was recently appointed manager for that company in Canada, and has taken up his new duties in the company's offices, 628-629 Coristine Building, Montreal. The company has been doing business in this country for over fifteen years and its operations are well known in all parts of the Dominion. Confidence has been shown in Mr. Harman's ability, by placing him in charge of this large and important territory.

Mr. A. W. Farnsworth, consulting engineer, of London, England, visited London, Ont., last week in the interests of English capitalists, who are looking for a location for the erection of a $5,000,000 steel plant. Mr. Farnsworth is visiting all the principal cities in Canada.

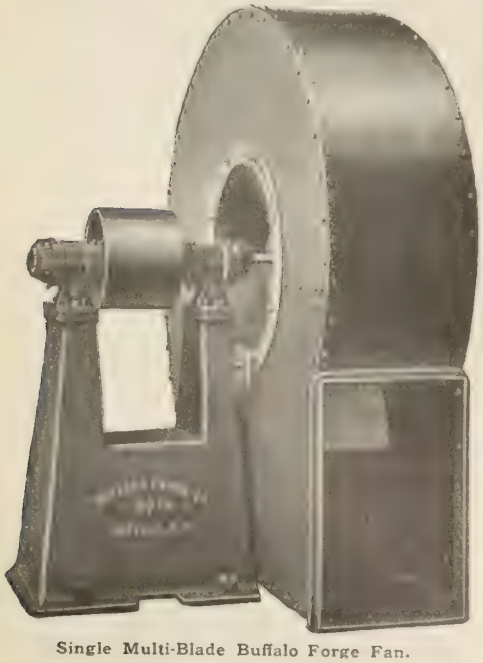
The death of Samuel O. Greening, president of the B. Greening Wire Co., of Hamilton, Ont., occurred in that city Aug. 31, in his sixty-fourth year. He had been ill for about a year, and his death had for some time been expected. Mr. Greening was born in Manchester, Eng., and came to Canada when quite young. Upon the death of his father, in 1877, he became head of the business, which, in 1899, was incorporated under its present style, and which, under his management, became one of the leading industries of Hamilton. He was a director of the Dominion Power and Transmission Co., and took an active part in the commercial and social life of Hamilton.

RECENT LEGAL DECISIONS.

Damages to the extent of $1,800 were obtained by Francis William Greene, from the Canada Foundry Co.

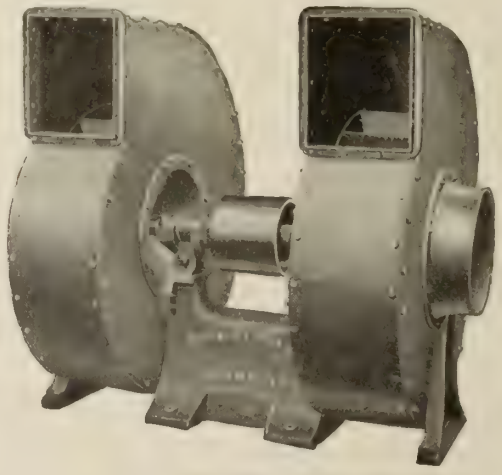
Greene had entered a suit against the company for $10,000 damages for injuries received on October 10, 1910, when an explosion occurred which threw molten pitch over him. As a result he was confined in a hospital for five months and is still under the care of a physician.

When the case came up before Mr Justice Middleton in the Jury Assizes, it was pointed out that the notice required by law, to be given within three months of the accident, that action was to be taken against them, was not given the defendants.



Upon Judge Middleton ruling that it was necessary that it be proved that defendants' case was not prejudiced by this lack of notice, a consultation took place between the lawyers, which resulted in the case being settled out of court.

William Fleming, who was injured in August, 1910, owing to a fuse blowing-out in a street car, upon which he was riding, was awarded $1,200 damages against the Toronto Street Railway Company, by Mr. Justice Middleton in the Assize Court. The amount asked by Fleming was $5,000.



From a paper dealing with the composition and treatment of iron and steel, it is noted that the centre of a casting is always coarser grained and weaker than the surface. Removing the skin of a casting reduces its strength per unit of cross-section. Bars cast horizontally are more uniform in strength and size than those cast vertically.

Sickness and invalidity insurance by co-operation between employer and worker is a subject to which too much attention cannot be given. Many American as well as European employers have established model institutions for complete social relief for their workers, and in nearly all cases such institutions have proved successful, not only from a humanitarian standpoint, but from a business standpoint.

The Robb Engineering Co., South Framingham, Mass., and Amherst, Nova Scotia, are building at the latter plant, two large rolling mill engines of 2,500 h.p. each. These engines, which are the first rolling mill engines to be built in Canada, are for the Dominion Iron and Steel Company

Double Multi-Blade Buffalo Forge Fan.

Mechanical Drawing and Sketching for Machinists*

By B. P.

A Series of Progressive Lessons Designed to Familiarize Mechanics With the Use of the Apparatus Necessary to Make Simple Drawings, to Encourage them to Realize How Important a Factor it is of Their Equipment, as Well as Being a Profitable Pastime.

IN this month's lesson we will consider the subject of screw threads. This should prove instructive both to the apprentice and also to the full-fledged machinist. The latter may be perfectly familiar with the method of producing a screw thread on an engine lathe, and yet find himself somewhat at sea when it comes to a question of making a correct drawing of such a thread.

Various Forms of Thread.

For the benefit of the apprentice we have prepared Fig. 1, which shows some of the most commonly used forms of screw thread. The pitch, p, of a screw is the distance from a point in one thread to the corresponding point in the next thread, measured parallel to the axis of the screw; and defines the distance the screw will advance into its nut in one complete revolution. The pitch is usually spoken of as being so many threads per inch; thus, 8 per inch means that there are eight threads and eight spaces per inch of length. It is also expressed as a pitch of $\frac{1}{8}$ inch.

The Whitworth thread, Fig. 1, is the standard form of triangular thread used by engineers in Great Britain and most other parts of the Empire. In it, the sides of thread are inclined to each other at an angle of 55 degrees; the depth, d, if the thread came sharp to the top and bottom, as shown by the dotted lines, would be equal to .96 p, where p is the pitch. The actual depth is only two-thirds of this, however, one sixth being rounded off top and bottom, as shown. To draw this thread, first set down a horizontal line A.B. and mark on it the pitch for the required number of threads. From the points thus obtained drop perpendicular lines as shown, and from these same points draw lines at 27½ degrees to these perpendiculars. Where these angular lines meet, draw another horizontal line C.D. The vertical distance between A.B. and C.D. is the theoretical depth, d, of the thread Divide this depth, d, into six equal spaces, and draw a horizontal line through the first division from the top and the first from the bottom. These two lines give us the actual depth of the thread, as shown rounded off top and bottom.

The Sellers thread is the standard form of triangular thread in the United States. Its sides are inclined at an angle of 60 degrees and the theoretical depth, d, is consequently equal to the pitch. An amount equal to $\frac{1}{8}$ d is cut off at the top and bottom, and left flat.

Another thread, frequently met with, is the common Vee thread. This is exactly the same as the Sellers thread would be, if the flattening at top and bottom were omitted. It is impossible to produce such a thread with scientific accuracy, besides the sharp points of course soon become worn and are easily damaged. Most authorities are urging the abandonment of the Vee thread, and it is to be hoped that it will soon be as extinct as the dodo.

The types of thread so far discussed all have ample strength, but their frictional resistance is very high. In order to reduce friction, the square thread is often used. In this type, the thickness and depth of the thread are equal to half the pitch, and the number of threads per inch is generally half the number required for a triangular threaded screw of equal diameter. Square threads are often used for transmitting motion, as in planing machines, lathes, etc. This form of thread is not as strong as the triangular type, and where the pressure to be transmitted is in one direction only, the buttress thread is more often adopted, the pressure in its case acting on the perpendicular side of the thread, as indicated by the arrow. This type is a combination of the triangular and the square threads, and has the strength of the former and the lower frictional resistance of the latter. Fig. 1 clearly shows its construction, although as it is not a standardized thread, the amount cut off top and bottom may vary in different shops. Sometimes this thread is rounded off instead of being left flat as shown in the cut.

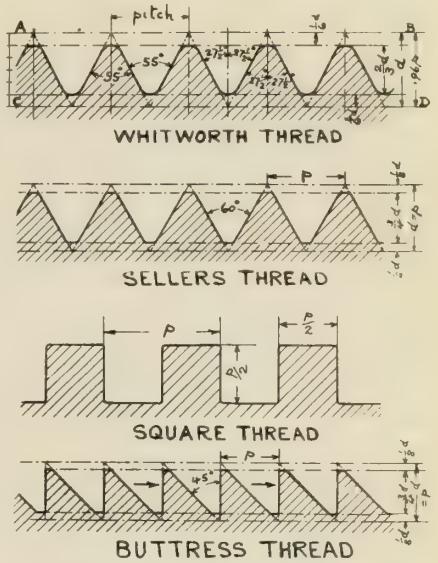

Fig. 1.—Drawing and Sketching.

Drawing a Helical Curve.

The edge of the thread in passing round the body of the bolt forms a helical curve, and the method of drawing this curve as it appears in a square threaded screw is shown in Fig. 2. Lay down the horizontal centre line, and at equal distances on either side of it draw two horizontal lines to represent the diameter of the screw over the threads. Set off the pitch along these lines and make the width of the thread equal to half the pitch. Draw horizontal lines to represent the depth of the thread, which is also equal to half the pitch.

It will be well to pencil all lines rather lightly at first, as parts of them will have to be erased later. Mark off the square threads, remembering that in a single threaded screw, such as we are now drawing, the threads at the

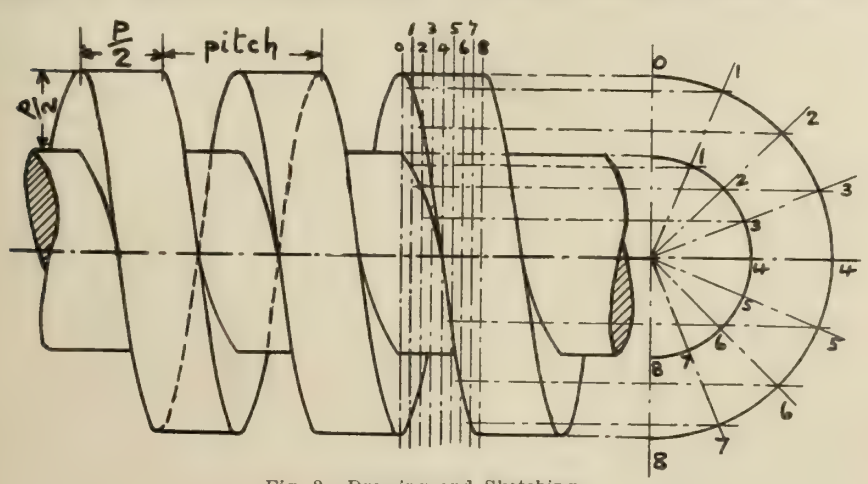

Fig. 2.—Drawing and Sketching.

* Eighth of a series of an instruction course.

top come opposite the spaces at the bottom. This is seen clearly in Fig. 3, which shows a nut for the screw shown in Fig. 2, but drawn to a rather smaller scale.

Next draw a half end view as shown to the right in Fig. 2. The smaller semi-circle shows the diameter of the screw at the bottom of the thread, while the larger is the diameter over the threads. Divide these semi-circles into any convenient even number of equal parts, say eight. Then divide half the pitch into the same number of equal parts, beginning at the corner of a thread, and drop perpendiculars through each point.

For a right hand thread, number these vertical lines as shown:—for a left hand thread, the order of the numbers will be reversed, that is, 8 will be on the left and 0 on the right. Next number the division points on the two semi-circles as shown in the cut, the order remaining thus, whether for a right hand or a left hand thread.

Points on the helical curve are obtained by the intersection of each vertical line with its corresponding horizontal line, the larger semi-circle giving points at the top of the thread and the smaller giving points at the root. The points thus obtained must be neatly joined up by a curve, in fact neatness and accuracy throughout are of the greatest importance, if the student wishes to make a drawing in which he can legitimately take some pride, when completed.

When one thread has been drawn by the above method of projection, it is best to make two templets of light wood or stiff cardboard. One should be cut to fit the curve at the top of the thread and the other to fit the curve of the root. By the aid of these templets the remaining threads may be quickly drawn. A little consideration will make clear the reason for the construction shown in Fig. 2. It is obvious that while a point in the screw passes through one of the divisions of the circumference, it will also move parallel to the axis of the screw, a like proportion of the pitch.

Fig. 3 shows a nut for a right handed square threaded screw. It is shown in section, and at first glance, the threads appear to be opposite hand to the right hand screw, Fig. 2. However, this is not really so. Remember that the nut is in section and note in Fig. 2 that the dotted curves in the screw are inclined the opposite way to those shown in full lines.

The curves of the thread in the nut are obtained by a similar method to that employed in Fig. 2. We have not shown the construction lines so fully, being of opinion that the student will derive more benefit from the exercise, if he studies out the matter for himself

Square threaded screws of coarse pitch are comparatively weak owing to the great depth of the thread, which reduces the body diameter considerably. The trouble may be overcome by sub-dividing the pitch into two, three, or more threads, each of which is ½, 1-3, etc., of the pitch in width and depth. This subject will be briefly treated at the beginning of our next lesson.

Owing to lack of space the final part of the September lesson was omitted. Referring to page 257 of the September issue, Fig. 4 shows a cast-iron chain barrel or drum for a jib crane. This is a good example of the usefulness of sectional views, because the longitudinal section shown gives all the information required by a pattern-maker of average intelligence. It will be a good exercise for the student to complete the drawing by the addition of an outside elevation and two end views.

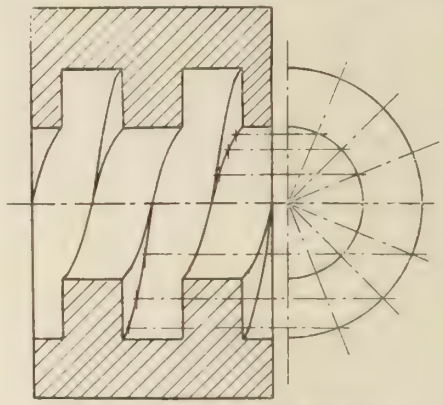

Fig. 3. Drawing and Sketching.

Student Exercises.

The long evenings are again here, and we propose setting a few exercises at the end of each lesson, which all students should endeavor to complete before the following issue appears.

1. Draw accurately a full size section of a Sellers thread bolt 4 inches dia., and 1¼ inches pitch.

2. Draw a square threaded screw 5 inches dia., 2 inches pitch. Show four or five threads, two being in section.

3. Draw a buttress thread in section. Show four threads; screw to be 3 inches dia., by 1 inch pitch. One sixth of the depth is to be cut off flat, top and bottom

THE NEW POLSON DRYDOCK.

THE new Floating Dry Dock now building at the Polson Iron Works, Limited, Toronto, Ont., is of the following dimensions:

Length	..600	feet.
Length over outrigger	642	"
Breadth over all	100	"
Breadth at deck inside	80	"
Breadth at top inside	84	"
Depth over all	35	"
Depth to dock deck	8	"
Lifting capacity	..9,000	tons.

At present, only two sections of 150 ×100 feet are being built, making an overall length of 336 feet, with a lifting capacity of 4,500 tons, and easily able to accommodate any vessel trading on Lake Ontario. At a future date, when larger vessels are expected to be on these waters, a 300 feet section will be built and added to the dock, making a total length of 642 feet, with a lifting capacity of 9,000 tons.

Constructional Detail-Bulkheads.

The dry dock is of U-shape section, each 150 feet length, being divided transversely by two watertight bulkheads, spaced 50 feet apart. These bulkheads are fitted intercostally between the three longitudinal bulkheads which run continuously from end to end. That on the longitudinal centre line is not intended to be watertight. Those at the side, located 20 feet on each side of the longitudinal centre line, are of watertight construction. These bulkheads consist of ⅜-inch plating, 5×3×⅜-inch vertical stiffeners spaced 30 inches apart, 5×3×⅜-inch horizontal stiffeners spaced about 7 feet apart, and shell and deck angles of 3½×3½×⅜-inch.

Constructional Detail—Framing.

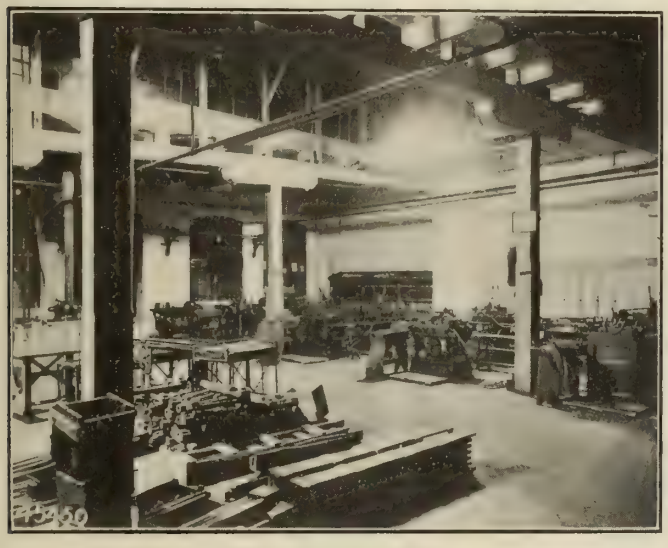
The framing consists of both longitudinal and transverse systems, the former being carried out between the wing bulkheads in the centre, and the latter, outside the wing bulkheads and on the walls. Solid floors are fitted transversely every 10 feet between the longitudinal bulkheads, and consist of ⅜-inch plating, with connecting angles of 3×3×⅜-inch and vertical stiffeners of 5×3×⅜-inch spaced 30 inches apart. Between these solid floors, are fitted the longitudinal frames of 6×3½×⅜-inch on the bottom and 12×25 lb. channel at the top. The former are fitted intercostally between the solid floors, while the latter run continuously from bulkhead to bulkhead. This longitudinal system of framing is completed by a continuous series of lattice work of 4×4×⅜-inch angles, with ⅜-inch cross ties and brackets securely connecting them to frames and vertical stiffeners.

The longitudinal framing summed up, comprises a non-watertight centre bulkhead, two side wing watertight bulkheads, and fourteen rows of frames and bracings. The transverse framing consists of a series of lattice work frames opposite every solid floor, of 6×3½×⅜ angle frames, ⅜-inch brackets and 4×4×⅜-inch bracings. The side frames of outer and inner walls extend from top to bottom continuously, and have beams securely bracketed to them about every 7 feet. Intermediate frames, fitted between each solid floor, spaced 30 inches apart, and extending from wing bulkhead to top, are of 6×3½×⅜-inch angles with ⅜-inch brackets connecting beams and stanchions.

SYSTEMATIC BUSINESS MANAGEMENT

Practical Articles for Managers, Superintendents, and Foremen, to Assist in Carrying on the Business Economically and Efficiently.

IMPORTANT LIGHTING CONSIDERATIONS.



By F. B. Allen
